The

Pharmaceutical Journal

AND

Transactions.

THIRD SERIES. VOLUME XXV.

FIFTY-FOURTH YEAR OF PUBLICATION.

1894-95.

LONDON:

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN,
17, BLOOMSBURY SQUARE, W.C.
1895.
CONTRACTIONS OF TITLES.

The following is a list of the contractions and the corresponding full titles of Journals most frequently used in "The Month." The titles prefixed by a Star are those of official Journals.

* Berichte = Berichte der deutschen chemischen Gesellschaft. Berlin. Once or twice a month.

INDEX TO VOLUME XXV.

(THIRD SERIES.)

FIFTY-FOURTH YEAR OF PUBLICATION.

The figures in heavy type refer to pages in the Supplements and Epitomes published from January 5 to March 30, inclusive.

Agriculture, Chemistry in its Relation to (Bastow), 720.
— Copper Compounds in (Girard), 1196.
Air, Liquid, Scientific Uses of (Dewar), 1181, 1206.
Airlé (Liday), 758.
Alberto, Dr.—Therapeutic Action of Calcium Borate, 1115.
Albumin, Action of Mould-Fungi on (Marchal), 608.
— Coagulated, The Solubility of, in Diluted Hydrochloric Acid (Moffat), 1028.
— Egg, Experiments with (Evans), 913.
— etc., Asperyl as a Reagent for (Rigler), 980.
— in Urine, Approximate Determination of (Rösler), 71.
— Soluble in Hydrochloric Acid (Harding), 914.
— The Solvent Action of Pepeln on, without Heat (Hombower), 984.
Albuminoids, Coagulation of (Ramsden), 885.
— Micro-Chemistry of (De Wevre), 71.
Alcohol, Recovered, Deodorising (Kadol), 856.
— Synthesis of (Bertholet), 20.
Alcohols, Oxidation of (Gaud), 453.
— Purification of, by Potassium Permanganate (Mammene), 541.
Algin, Free Iodine in, 963.
— Influence of Arsenic Acid on (Boulliau), 541.
Alkaloids, Determination of (Dietrich), 962.
— Localisation of, in Plants (Cautiaux), 435.
— of Berberis (Pommerehne), 1090.
— of Scenecio Vulgaris (Grandval and Lajoux), 1195.
Allen, A. H.—Glycerin of the Market, 832.
— A. H.—The Determination of Glucose, 880.
— C. B.—Minimum Cutting Prices, 117.
All Round the B.P. (Laing), 511.
Almond Oil, Essential, Oxidation of (Schmeltz), 989.
Alöf, Note on (D. R. Brown), 906.
— (Serre), 889.
Alpam (Hooper), 231.
Alum, Glycerin of (Dutton), 963.
— in Bread (Bigelow and Hamilton), 842.
Alumina in Plants (Bertalot and André), 754.
— Reduction of, by Carbon (Mossan), 541.
Aluminium Beroformate (Martenson), 438.
— Carbide, Crystallised (Mossan), 71.
— Corrosion of (Liveridge), 102.
— Phenol and (Balland), 834.
— Soldering (Olivon), 508; (Richardson), 542.
— Writing on Glass with (Margot), 838.
Alumnol, Formula for dispensing, 1116.
Amber, Sucininate and other Varieties of (Aungst), 755.
American Pharmacy Law in (Editorial Remarks on), 942.
— The Condition of Pharmacy in (Beringer), 601.
American Chemical Society (Schweinitz), 283.
— Pharmaceutical Association (Oldberg), 225; (Kremer), 280; (Kebler), 285; (Meeting at Asheville), 319; (Papers read at the), 363; (Kerr), 532, 1049, 1159.
— Pharmacy Fair, 44.
— Recipes for Beverages, 70.
Amides, Acid, and Aromotic Nitriles, Hydrolysis of (Sudborough), 976.
— The Action of Nitrosyl Chloride on (Tilden and Forster), 975.
Ammonia, Aroma of Spirit of (Liver- seege), 722; (Brayshay), 772.
— Household or Cloudy, 989.
Ammoniated Mercury, Ointment of (England), 69.
Ammonium Cyanate into Urea, Transformation of (Walker and Hamley), 1211.
— Succinate as a Uterine Anti-Spasmodic (Remy), 935.
— Thio-Acetate (Schiff and Taregi), 107, 110, 905.
SUPPLEMENT TO PHARMACEUTICAL JOURNAL

INDEX
(October 13, 1896)

Amyl Valerianate in Hepatic Colic ('Blanc'), 1167.
Analyt, Death of a County, 1217.
Analytica, Public, in Australia, 905.
Animal Chemists, Conflicting Evidence of, 1017.
— Notes, 1123.
Anders—Guialcoul in Algajla, 1086.
Anderson, W.—The Introduction of the Metric System into the British Pharmacopoeia, 575.
Anesthetic, Constitution of (Heil), 961.
Animal Extracts (Stuart), 17.
Animals in Sterilised Air (Kijanowski), 963.
Annual Meeting, Editorial Comments on the, 566.
Annulante, Death of, 278, 318, 942.
Antichlor, H.—The Remuneration of the Assayers, 504.
Anti-Cancer Serum (Bows and Petersen), 1189; (Emmerich and Scholl), 1135.
Anil-Diphenolic Serum, 278, 291, "298, 342; (Lister), 582.
Anti-Diphtheria, The, Illustrated, 209.
Antidotes and Antitoxins (Harnack), 545.
Anti-Dyspepsium, 356.
Antidysmenia, Fyretime, and Phenol (Weiler), 19.
Antimoniac Acid (Sorono), 626.
Antimonium Tartaratum, B.P., 169.
Antimony, Precipitation of, from Solutions of Potassium Antimony Tartarate (Long), 710.
—Biphede (Bohigury), 255.
Artikel Poison Stopper (Hargrave), 363.
Antipyrene Amygdalate (Tussol) in Whooping Cough (Rehn), 959.
— and Spirit of Nitrous Ether (Schack), 71.
— and Tolypyrine, Distinction between (Stook), 19.
— Cause of Eruption (Gaston), 1066.
— Determination of (Schack), 71.
— Mandelate in Whooping Cough (Rehn), 912.
Antiperspirants, Formulæ and (Effront), 72.
— Novel, 989.
Antistreptococcic Serum, 954.
Antitetralazin, 434.
Antitoxic Serum for Snake Poison, 1302.
— Serum, The Supply of, 590.
"Antitoxin" and "Antitoxine," 454.
— Diphtheria, in Russia, 954.
— Diphtheria, Sale of, in Zurich, 1079.
— Diphtheria, in Bavaria, 1109.
Antitoxine Treatment of Diphtheria, 610.
"Antitoxine" as a Trade-mark, 93.
Antitoxins, Antidotes and (Hartshack), 548.
— (Editorial Remarks on), 459.
— Medication by (Bruxton), 866.
Antwerp, International Exhibition at, 117.
Apopilia pro Electriectate anti (Hedley), 1018.
Apostolides, M. G.—Preparation of Santonin Biscuits, 960.
Apostleman Act, Proceedings under the, 411.
— Hall, Banquet in, Dublin, 1112.
Apparatus, Correction of, in Physico Chemistry, 890.
Apprentice, A Chemist's, Drowned (York), 1215.
Apprenticeship in Pharmacy (Editorial Remarks on), 941.
— Proposed Revival of, in the City of London, 1215.
Aquas Camphorae (Jones), 856.
— Chloroformis and Aqve Camphorae (Elborne), 551; (Martindale), 589; (Wells), 620; (Elborne), 639; (Wright), 640; (Jones), 855.
Arabino-chloro-lose (Richet), 643; (Hammar), 175.
— Areae Cacothoe (Oesenbrid), 72.
— Nut, Development of the (Oesenbhr), 72.
Argon (Rayleigh and Ramsay), 650, 676; (Stoney), 696; (Rayleigh), 901; (Berthelot), 103; (Sedgwick), 111; (Berthelot), 111.
— and Helium (Brauner), 1159.
— and the Periodic Law (Brauner), 969.
— in Minerals (Hodgkinson), 1089.
— Isolation of, by Lithium (Gunts), 1021.
— The Attempted Isolation of (Mossan), 1077.
Argonio (Liebrecht and Rohmann), 1193.
Artistol for Burns (Haas), 545.
Artistolochia Gigas (Hill), 230.
— H. E.—The Structure of the Sugars, and Their Artificial Production, 1215.
Aromatic Acids, On the Derivatives of (Meyer), 710.
Arrowroot in Australia, 60.
Arsenate of Lead as an Insecticide (Brown), 1103.
Arsenous Acid, Influence of, on Alge (Boulliac), 641; Bettendorf's Test for (Curtman) 543.
— in Dentistry (Johnson), 991.
— in Epithelium of Face (Wych), 912.
— in India, The Sale of, 967.
— in Phosphates and Hypophosphites (Schlagdenhaufen), 542.
— in Pills, 1079.
— or Arsenium ! 88.
— or Phosphates ! 154.
— Origin of the Word, 986, 1017.
Arsenie-Iva, Liquor, Rapid Preparation of (Grahn), 1219.
Arsenious Acid, Salts of (Stavenhagen), 692.
Artemisia (Merck), 834.
Arthur, C.—Death of, 42.
Artificial Rubber, 383.
Arts and Industrial Exhibition at Belfast, 1082.
Arneilbuch, German, Appendix to the, 780.
Asbestos, Imports of, into Sind and British Baluchistan, 316.
— Impurity of, 1139.
— in Abortion and Gynecology (Warman), 569.
— Plants, The (Hollins and Aitchison), 131.
Asbestos as a Reagent for Alumina, etc. (Riegler, Frank), 960.
— in Infantile Diseases (Moncorvo), 1166.
Asbestos Filter, A Novel, 544.
Asocchytia Pla, An Injurious Fungus on Peas (Frank), 1083.
Aseptic Surgery, Aids to (White), 191.
Asphalt Industry, The Trinidad, 374.
Assay of Ipecacuanha, Notes on the (Cripp), 1083.
Asthmatisation of Green Plants by Glycoerin, 645.
Atmosphere, Discovery of the Composition of the (Cavendish), 651.
— New Constituent of the (Rayleigh and Ramsay), 134; (Wanklyn), 154; (Kelvin), 474; (Rayleigh and Ramsay), 650; (Wanklyn), 36.
— The Composition of the (Vaughan), 1192.
Atmosphere in the Higher Atmospheres (Remitz), 437.
Atomic Theory, The, and Death (Lasing), 928.
— Theory, The (Brown), 962; (Elborne), 962; (Lasing), 961.
Atte, The Shapes of (Brown), 866.
Audi Alteram Partem (One of the Young Generation), 770.
Aurantier Aesculifolium Liquor (Martindale), 9-4.
Austen and Broadhead—Blocks for Drying Precipitates, 1193.
— J—Notes on Hops and Hop Culture, 720.
Australia, Public Analysis in, 73.
— South, Pharmacy in, 445.
— Western, Pharmacy in, 445.
— Western, The Pharmacist in (Pitpatrick), 1064.
Australian and Indian Notes, 59, 885.
— Brookline, 59.
Austria, Pharmaceutical Ethics in, 1049.
Austro-Hungary, Pharmacy in, 448.
Austro-American Doctor, Ann. 1113.
— Process for Aqua Chloroformi Am (Elborne), 581; (Martindale), 619; (Wells) 620; (Elborne), 639; (Wright), 640.
Aventoom, Surgeon-Major—Chinaman in Dunesteyn, 1189.
Awend, E.—Suicide, 765.
## INDEX

### B

Bach, A.—Hydrogen Peroxide in Green Plants, 173, 645.

Bacteriology—Inhibitory Action of Metals upon the Growth of (Bolton), 1028.

- Thermophilic (Mackayden and Biakal), 253.
- Variations of (Chauveau and Phaleix), 963.

Bacteriological Institute in Dublin, Formation of, 1136.

- Wonders, 881.

Bacteriology, Classes in, 259.

- in its Practical Aspects (Hewlett), 819, 893.
- of Clothes (Leitz), 1135.
- Progress in, Specialism in Pharmacy begotten by, 635.

Beayser—Carvstrea, 992.

Badghi and Bashorah, Trade of, 276.

Bailey, L. H.—Evolution Among Plants, 1000.

Ballion, Prof.—Tabanarmona Iboga, 436.

Balance-Adjusting Device (Green),

- Novel Adjunct to the (Kuhlmann), 929.

Baldoch, J. H.—Starch as a Mountant, 1092.

Balkwill, F. P.—Botanical Curiosities, 1056.

Ball, A. W.—Anti-Extrem Cutting, 1220.

Ball, Brighton Chemists', 104.

- Chemists', The, 363, 95.

- Edinburgh Chemists', 25.

- Junior Pharmacy, 53.

- Manchester Pharmacy, 18.

Balland, M.—Pheno1 and Aluminum, 834.

Ballard, M.—Guaiacol Phosphate, 543.

Balsem of Peru, Turpentine in, 19.

Bancroft, T. L.—Carissa Ovata, 253.

Bandages, Sterilised (Turner and Krupka), 1196.

Barbier and Bouvans, Essence of Perguionium, 172.

Barbour, S.—Pharmacopoeia Suggestions, 885.

Barclay, J.—Laboratory Notes, 722.

Bard, E. B.—Research Laboratory, 1108.

Barometer, An Improved Form of (Collie), 551.

Barth, M.—Assay of Zine Salts, 642.

Bartholow, Dr.—Papain for Expulsion of Tisra, 1139.

Bastin, E. S.—Starch of Casso, 173.

- E. S.—Structure of Sanguinaria Canadensis, 644.

- E. S.—Veratrum Viride, 963.

Battery Cell, Inexpensive, 110.

- Compact Portable, 646.

Battandier, M.—Reactions of Chelidonine, 753.

Bavary, H.—Antimony Sulphide, 383.

Bavaria, Diptheritic Antitoxin in, 1109.

Bay, Oils of (Power and Klaser), 964.

Bay, Dr.—A New Element, 642.

Bayless Drug "Company," The, 889, 1019.

Bayley, Dr.—Is Oxygen a Mixture ?, 881.

Becher, C.—Solvency in Oils of Cadin, 545.

Beckman, E.—Determination of the Purity of Milk, 883.

Beans of Europe, The, 1051.

Beer, Fluorine in (Stefanwil and Mann), 1124.

Beenaar, A. (of Marie), 172.

- Adenona (Kremel), 546;

Silveradis, 542; (Kahler), 835.

- and Paraffin, Admixture of, 421.

- as a Drug, 9.

Blachard and Unbleached (Unna), 540

Beland and Chassy—Wood Creosote 73.

Behring and Roux—Diptheria Antitoxin, 938.

Beltedorff—Casein in Ointments, 1157.

Belgium, Pharmacy in, 448.

Belladonna Plaster (Box), 878.

- Root, Aludated (Lowes), 73.

- Standardised Preparations of (Cripps), 793.

Bennett and Subscriptions for 1894, 733, 781.

- Fund, The (in 1894), 569, 712.

- Benzol Acids, Dihro-Substituted (Sudbrough), 976.

- Berberis, Aloldriols of (Pommeren), 1155.

- Berenger, G. M.—The Condition of Pharmacy in America, 601.

- Berlin Pharmacological Institute, 1159.

Bermuda, Pharmacy in, 447.

Bergen, M.—Borsaliclyte, 434.

- Barth and André—Alumin in Plants, 754.

- and André—Respiration in Plants, 436.

- M.—Jodides of Mercury, 172.

- M.—Platinum as an Accumulator, 236.

Berti—Preservation of Powdered Ergot, 1167.

Bertram and Kürstner—The Constituents of Cassia Oil, 98.

Bertrand and Maillevre—Pectase and Pecto Fermentations, 644.

- and Maillevre—Pecto Fermentation, 542.

- Lacosum and Lacoc, 75

Beverages, American Recipes for, 70.

- Formula for (Merrit), 1164.

Bigelow, W. D., and C. C. Hamilton—Alum in Bread, 642.

Bio-Chemistry, The Importance of the Study of (Schweinitz), 255.

Bird, F. C. J.—Laboratory Notes, 169.

Birmingham, Pharmaceutical Education in, 223.

Biro and Jeanner—Fungi of Papus, 173.

Bismuth, Atomic Weight of (Schneider), 641.

- Nitromophenol (von Heyden), 435.

- Nitrosaliclyte (Caunes), 694.

- Oxyaliclyte (Dott), 582.

- Pyrogalpte (Vittorio), 438.

- Salicylate as a Dressing (Brindel), 968.

- Solubility (Casarius and Racchobetti), 454.

Bismutho (Riadler), 1181.

Blackman, F. F.—Carbon Dioxide Exchanges in Plants, 835.

Blanc—Amyl Valerianate in Hepatic Cells, 1187.

Bland’s Pill (England), 68; (Ince), 131.

Blight, American, Application for the Prevention of the, 1083.

Blistering Principle of Holigarns, The (The Hooper), 1197.

Blocks for Drying Precipitates (Austen and Broadbent), 1198.

Blondeau et Cie.—Minimum Cutting Prices, 960.

Blood, Circulation of the (Servets), 386.

- Micro-organisms in the, Staining (Vincent), 73.

- Serum, Preparations of, as Dressings for Wounds, 682.

Box, P.—Ointments, 863.

- Belladonna Plaster, 878.

Bödiker, E.—Determination of Chlorine, 938.

Bohland—Preserving Organised Urinary Sediments, 1196.

Boland, L. de—Volume of Salts in Solution, 833.

Bokro, T.—Influence of Calcium and Magnesium on the Growth of Plants, 1176.

- Purification of Water by Green Plants, 856.

Bolton, Dr. M.—Inhibitory Action of Metals upon the Growth of Bacteria, 1026.

- of the Year, 1894, 576.

Boormma—Medicines of the Dutch West Indies, 1091.

Borale, 595.

Borax in Rhizitis (Manshojd), 1132.

Borsood and Girard—Calcium Permanganate for Purifying Water, 1092.

Boride of Iron (Molisan), 755.
Cocaine in Labour and Neurasthenia (Dabbe), 912.
- Solutions, Strength of, 904.
- The Preparation of, 375.
- Cooks, Mr. James, Presentation to, 318.
- Coco-Nut Stearin as a Basis for Suppositories (Thompson), 185, 210.
- Cocoa, An Admiral on, 57.
- Cod-Liver Oil and Chemistry (Editorial Remarks on), 968.
- - Liver Oil as a Tonic (Robinson), 912.
- - Liver Oil, Colour Reaction for (Rössler), 1116.
- - Liver Oil Emulsion, Alleged Substitution of, 1111, 1187.
- - Liver Oil, Phosphated Emulsion of (Marfan), 249.
- - Liver Oil, The Alkaloids of (Schölltebeck), 585.
- - Liver Oil, To Flavour (Duquesnel; Pares), 116.
- Codolene Sulphate with Hydrobromic Acid (Duncan), 554.
- Codex Medicamentarius, Supplement to, 695.
- Coffin - Treatment of Periarthritis, 1086.
- Cold Cream, Formula for, 30.
- - Extreme, Burning Effects of (Picot), 103.
- Colouring Matter of Gentian (Howell), 1196.
- Collisn, 356.
- Collodion, Depilatory, 1087.
- Colour Screens, Chromatic, 297.
- Colours in Photography (Vogel), 106.
- Combustible - Treatment of Lead Collo with Large Doses of Olive Oil, 1187.
- Combustion in the Electro Arc (Gibault), 992.
- Companies, One-Man," Important Decision with Regard to, 1110.
- "Company" Pharmacy? Can we Stop (Care), 509.
- - Pharmacy at Torquay, 882, 1019.
- - Trading (Editorial Remarks on), 1:97.
- Compressed Gases, The Dangers of (Editorial Remarks on), 321.
- Container, Novel (Martin), 649.
- CONFERENCE, BRITISH PHARMACEUTICAL.
- Bell and Hill's Fund, Presentation of Books from the, 203.
- Blue List, The, 1078.
- Bournemouth, Proposed Meeting at, 203.
- Delegates, Reception of, 108.
- Executive Meetings of the, 37, 136, 320, 807, 1108.
- British Pharmaceutical Conference - continued.
- Formulary Committee, Appointment of the, 203.
- Letters of Apology, Receipt of, 108.
- Liverpool, Proposed Meeting at, in 1896, 953.
- Officers, Election of, 204.
- Oxford, Meeting at, at 7, 77; (Editorial Remarks on the), 91; 101, 123, 196, 155, 177, 197, 242, 549.
- Papers read at the Oxford Meeting (see under subjects or authors' names).
- Place of Meeting for 1895, 203.
- President's Address (N. H. Marrin), 101.
- Votes of Thanks, 205.
- Work during 1894, 571.
- Conference, The Sanitary (Meeting at Manchester), 1051.
- - International, of Hygiene and Demography, The VIIth, 195, 224, 243.
- Conti in Eier (Sanctile), 1195.
- Conjoint Examinin' Board, The, 117; (Practical Chemistry Syllabus), 47.
- Conn. H. C. - Improving the Flavour of Butter, 909.
- Conroy, M. - Adulterated Acetic Acid, 862.
- - M. - Note on the Relative Alkaloidal Values of Leaflets and Leaf-stalks of Jaborandi, 981.
- Consumption and its Prevention (Editorial Remarks on), 919.
- Cooks, Professor J. F. - Death of, 129.
- Cookery, the Spirit of (Thudichum), 895.
- Copper Compounds in Agriculture (Girard) 1196.
- - Hemol, 1024.
- - In Peas (Bristol), 18; (Edmonston), 72.
- - Reaction, Sensitive (Sabatier), 172.
- - Sulphate, Disinfection by (Vincent), 642.
- - Zinc, etc. Separation of (Warren), 733.
- Coppet, M. - Maximum Density of Water, 644.
- Corder, Mr. Octavius - Retirement of, as Examiner, 298.
- Corin - Dispensing of Digitoxin, 1139.
- Cornum and its Citrate in Uterine Affection (Lewia et al.) 1055.
- Correction of Aperius in Physiological Practice.
- Corrected to, 20, 44, 70, 431, 432, 704, 792, 812, 832, 903, 960, 992, 1016, 1140.
Electroty, Atmospheric (Schuster), 73.
— Removal of Stoppers by (Hill), 1219.
Elecro-Coppering, 1191.
— Chemical Society, The German, 956.
Electrolysis, A Theory of, 881.
—and Chemical Industry, 969.
Electrolytic Phenomenon, An Interesting (Reed), 1090.
Element, A Supposed New, in Basalite (Barry), 642.
Elements, New, The Revolutionary Value of, 929.
Elhman, Sons, and Co.—Anti-Extreme Cutting, 1140, 1192.
Elliot—Strychnine as an Antidote for Snake Bite, 990.
Emotions (Adam), 652.
Emetin (Paul and Cownley), 111, 373, 641, 690.
Emmerich and Scholl—Anti-Cancer Serum, 1135.
Emmury—Lysite, B.P. (Mason), 170; (H. G. W.), 190; (Fletcher, Ince), 210; (Clover), 250.
Empleeurum Serrulatum (Umney), 756.
Emulsion of Castor Oil, 102.
Emulsions, 1021, 1098.
— Terebene (Lowen), 69.
— Suggested B.P. (Henry), 878.
Erog, Ammoniated Tincture of (Hornblower), 242.
— of Rye (Burns), 1615.
— Preservation of Powdered (Ber
tini), 1167.
Eschbaum, F.—The Size of Drops, 1196.
Escherich — Pilocarpine Hydro
carbide in Frurigo, 969.
Essences, Flavouring (Galen, Jun.), 913.
Essential Oils in their Relation to the B.P. and Trade (J. C. Umney), 946, 977, 1039.
Élard, A.—Varieties of Chlorophyll, 173, 754.
Ether, Illegal Sale of (Cookstown), 1183.
— Pure (Thorne), 642.
— Purification of (Eckenberg), 13.
Ethics, A Point in Trade, 896.
Ethoxy-Naphthalene, Sulphonation of (Lapworth), 933.
Ethyli Nitrile, Pure, 19.
Ethylen-Ethynyl-Diamine, 1191.
Everett, J. G.—Syr. Ferri Iodidi, 739.
“Ewing” Prize Pharmacy Competition, Result of the, 1015.
Eucalyptol, Preparation of (Holmes), 502.
Eucalyptus Oil (Holmes), 501; (Attewell), 540.
Evans, R. J.—Experiments with Egg Albumin, 913.
Evolution Among Plants (Bailey), 1009.
Examination, Education and (Long), 69.
— Preliminary, Should the Scope of, be extended? (Conolly), 651.
— The Major (Editorial Remarks on), 865; (Wills), 879; (“Nux”), 879; (Dyson), 903.
Examinations and the Relative Positions of the Teaching and Examining Bodies (Rhoden), 929.
— Pharmaceutical, 219.
— Pharmaceutical, in Japan, 953.
— Pharmaceutical, in Massachusetts, 881.
— Pharmaceutical, Massachusetts, Failures at, 1049.
— The, in 1894, 663.
Examiners, The Appointment of (Young), 649.
Excruciations in Children, Ointment for, 1065.
Exhibition, Arts and Industrial, at Belfast, 1089.
— of Economic Plants at the Hague, 929.
— of Preserved Food Stuffs, 896.
— Pharmaceutical, at Brussels, 1012.

PATENT SPECIFICATIONS PUBLISHED—
January: Magnesium Hydrate (D'Andrie), 81; Embrocation (Simmons), 31; Preparations of Coffee and Cocoa (Lebre), 81; Supplying Liquids from Bottles (Bragg), 81; Hair-dye (Lambe), 31; Vermin Killer (Wagemann), 81; Bed-urinal for Females (Grosse), 31; Distributing Antiseptics and Disinfectants (Morin), 31; Funnel (Brown), 81; Ignit of Rye (Bouringer), 80; Hydrogen Peroxide (Wolfenestein), 40; Bismuth Oxylodide Gallate (Ludy), 40; Ammonia Soap (Heaton), 40; Cellulose and Bye-Products from Wood (Cross), 40; Condensed Milk (Hansen), 40.

February: Double Soda Salt (Johnson), 51; Petroleum Compounds (Werygan), 51; Filter (Lepoxomb), 51; Broschits and Van Estells (Coles), 51; Caps for collapsible Tubes, etc., 51; Oxide (Schneller), 51; Arometer (Lohnstein), 51; Ferrocyanide of Potassium or Sodium (Hetherington), 51; Alloy of Potassium or Sodium with Lead (Hetherington), 51; Making Compressed Tablets and Pills (Thomas), 51; Electrolysis (Richardson), 51; Sodium or Potassium Cyanide (Hetherington), 76; Spectacles (Rintoul), 76; Trusses, etc. (Simmons), 76; Hydrochloric and Hydrobromic Acids (Lorenz), 76; Electrolytic Reduction of Metals (Oliver), 76; Tannia (Hagemann), 88; Lead Salts (Tibbits), 88; Cocoa (Boisseler), 88; Bottle-stoppers (Weber), 88; Carls (Leach), 88; Seasickness Preventing (Waldron), 68.
INDEX.

18, 1895.

April: Filtra.tion (De Mol), 911; Funnels (Holli), 911; Sieri-fising Fluids (Loores), 911; Disinfecting (Hermite), 911; Capsuling or Plating Bottles, etc. (Fichler), 911; Hernia Trusses (Knowles), 911; Making Alkaline Sul-phides (Plocher), 911; Compounds, etc. (van der Sluys), 911; Bottle Stoppers (Mann), 911; Evaporating Liquids (Caldono), 911; Filters (Brandenburg), 911; Sulphuric Acid (Wacker), 911; Extracting Gold and Silver from Ores (Nicholson), 933; Venti-lating and Sterilising the Air of Hospitals (Brophy), 933; Bottle for Aerosol and Other Liquids, etc. (Kilby), 933; Cellulose Acetate (Crosu), 934; Disinfectant or Antiseptic (Walker), 934; Making Nitric and Hydrochloric Acids (Campbell), 934; Alloys (Vantin), 934; Sterilising Milk, etc. (Zweibohmer), 934; Extracting Metals from Ores (Bonehill), 938; Aseptically Sealed Beverages (Schwartz), 938; Breast-pump (Golferi), 938; Softening Water (Hooper), 938; Treating Gold and Silver Ores (Thomson), 958; Saturating Liquids with Gases (Beins), 958; Vanillin (Haarmann), 958; Trusses (Kraven), 959; Milk Product (Henderson-Ayres), 959; Dental Clamps (Richter), 969; Tooth-brushes (Brook), 969; Nickel and Cobalt (Manhes), 1023; Labelling Poisoning Bottles, etc. (Mand), 1023; Sodium and Potassium (Vaunit), 1028; Sulphur Candy, or Fumigators (Kingsett), 1029; Deodorising Petroleum, etc. (Temple), 1023; Inhaler (Quaglio), 1023; Massage, etc. (Schaefir), 1023; Filter (Chamberland), 1023; Stand for Surgical Dressings (St. Dalmes), 1054; Gold Foil for Dentistry (de Trey), 1054; Tooth-ache Cure (Hathorn), 1054.

June: Filtering Cotton - Seed Oil (Aspliy), 1190; Organic Iodides for Pharmaceutical use (Newton), 1190; Raw Materials, etc. (Mann), 1190; Clinical Thermometers (Peroni), 1190; Potassium Chlorate (Bayer), 1190; Bottle Stopper (Rosenfeld), 1190; Bottle Stopper (Stein), 1190; Purifying Metals (Krupp), 1190; Ambulance (Haywood), 1190; Liniment (Dillates), 1190; Pads for Intercostal and Hemorrhoids (Blumenthal), 1190; Purifying Sugar, etc. (Sibth.), 1218; Preserving Meat, etc. (Lake), 1218; Desert Trumpet (Leigl), 1218; Bye-products from Sodium carbonate Manufacture (Greenwood), 1218; Making White Lead and Ammonia Salts (Wolox), 1218; Ammonium Sulfate (Mackay), 1218; Alkaline Ferrocyanides (Crowther), 1218; Electrolysis (Gautier), 1218; Hemoglobin (Hommel), 1218; Fessary (Weisgerber), 1218; Sulpho-cyanate (Al-bright), 1218; Abdominal

### INDEX.

**Pharmaceutical Journal. XXVII**

**Seneca Root.** Adulteration of, 1091.
- Root, Salicylic Acid in, 1195.

**Senna Leaflets.** Structure of, 334.

**Sensitive Movements of Plants (Macfariane),** 1060.

**Serre, C. A.**—Alolin, 839.
- C. A.—The Manufacture of Milk Sugar, 624.

**Serum, Anti-Cancer (Bovens and Petersen),** 1189; (Emmerich and Scholl), 1155.

**Anti-Diphtheritic, 278, 291, 298, 311.**

**Anti-streptococcic (Marmorek),** 954.

**Anionic, for Snake Poison (Editorial Remarks on),** 1202.

**Antitoxic, The Supply of,** 930.

**Blood, Preparations of, as Dressings for Wounds,** 682.

**Sharp, G., and Hoeseon—Cactus Grandiflorus,** 253, 416.

**Sheffield Microscopical Society,** 426, 701, 721, 78, 96, 113.

**Pharmaceutical and Chemical Society, Guest to the,** 866.

**Pharmaceutical and Chemical Society (Inaugural Address—Allen),** 303; (Inaugural Meeting and Annual Dinner), 320; 426, 518, 54, 720, 685, 922.

**Shopbreaking at St. Hilaire,** 5124.

**Shorey, E. C.**—Citic Acid in Cane Juice, 316.

**Short,** F. W. Testimonial to, 1169.

**Siam.** 5-Cervin Products of (**De Bunsen**), 1030.

**Scl.; W.**—Scresc Ducts, 73.

**Signs and Symbols, Chemical and Pharmaceutical (Tickle),** 365.

**Siliceous Amorphous Phosphates.** Preparation of (**Vigorouix**), 642.

**Silicous Dr.**—The Evolution of the British Pharmacopoeia, 900.

**Silver Amalgam.** Resiluable Change in (A little ton), 701.

- Blackened by Carbon Bisulphide-Extracted Castor Oil, 692.

- Osmantments, Ancient, from Peru. The Composition of (Walker), 701.

- Sulphide (Ditte), 642.

**Silvering Mirrors (Louvriol),** 910.

- (!) Mixture, Explosion of (**Salzale**), 610.

**Silverweed, R. B. G.**—Adulteration of Beeswax, 620.

**Simmonds, P. L.**—Shrink, 1165.

**Skinner, Dr. M.**—Caffeine in Asthma and Diseases of the Respiratory Organ, 963.

**Skin Diseases, Medicated Crayons for (**Mantie**), 963.

**Skinner, H.**—The Early History of Phosphorus, 934.

**Slocum, Dr.**—Cephalin Thieves in Leucorubus, 1138.

**Smith, R. R.**—Chemical Works Inventory, 1098.

- F. F.—The Atomic Weight of Tungsten, 888.

**Smokers' Givings, Treatment of (Vina)), 1115.
- Snake Bite, Cure for, 1112.

- Bite, Strychnine as an Antidote for (Elliot), 990.
- Poison (Halliburton), 645, 585.

- Poisons, Antidotes to (Maiden and Hamlet), 59.

- Sneezeing (Spyler), 404.

- Soap Basis for Linaments, A (Lucas), 470, 270.

- Supersatted, The Preparation of (Moffat), 41; (Johnson), 169.

- Soave—Richlin, 1194.

**Society, Founders of the (Munbray),** 1184.

- of Arts, 906.

- of Arts (Conversatione), 1214.

- of Arts, Presentation of the Albert Medal of, to Sir Joseph Lister, 983.

- of Chemical Industry, 907, 1017; (Annual Meeting), 1158.

- of Chemical Industry, Annual Meeting of the (Editorial Remarks on the), 31, 44.

- of Druggist-Apothecaries in Edinburgh, 984; (Macnatas), 973.

- of Public Analysts (Annual Meeting), 20.

**Soda.** Production of (Castner), 251.

- Water for Burns (Gowalowsky), 1167.

- Water! What is it, 290.

- Sodium and Potassium Phosphides (Joanni), 353.

- Bisulphite, Kocrystallisation of (Evans and Desch), 1096.

- Uthylate, Action of, on Deoxybenzoin (Sudborough), 976.

- Fluoride in Tubeculosis (Bougeois), 1168.

- Bryosulphite and Chloral in Painful Dyspepsia, 1055.

- Solicylate and Caffeine, Combination of (Dellasuda), 88.

- Solicylate as a Clearing Agent (Leos), 13.

- Cholosulphate in Purgitas, 1166.

**Soil Water, Action of, on Vegetation,** 1176.

**Solanaum Carolinenses in Eilepsy (Carr), 1065.

**Solubility, Lysimeter for Determining (Roe), 647.**

- of Gases in Water under Varying Pressures, The (Perman), 1014.

**Solubility of Quinine in Alkalies (Duamer and Denaux), 816, 929.

**Solution, Volume of Salts in (de Bolsbanaun), 833.

**Solutions, Determining the Density of (Kohrmanch and Hallwache), 687.**

- Feeding Points of (Nerst and Abegg), 961

**Soothing Syrup, The Dangers of,** 906.

**Sophistication a Century Ago (Ward), 882.**

**Spain—Mace Oil, 1195.

**Speasgrists, The (Ince), 499.**

**Spasmotin (Böhhringer), 251.**

- Specific Gravity, Determination of, 1143.

**Spectroscopy, The, and Photography,** 1186.

**Spectrum of the Electric Discharge (Living and Dewar), 171.

- The Inviolae (Higgins), 1186.

**Spencer, H.**—Priest and Medicine Man, 1152.

**Sphenolizin (Bohhringer), 251.

**Spyler, Dr. Bonsae—Sneezing, 404.

**Spice and Lavender, Oils of (Massol), 644.

**Spirit, Duty on, Reduction in the,** 1018; (Editorial Remarks on), 1029.

**Spiritus Athenæus Nitrois, Report on (**Smith**), 809.

**Sponges, Cultivation of,** 1194.

- Loaded, 1092.

**Spring, W.**—Allotropic Mercury Sulphides, 541.

**Spurn, Tubercular, Staining Fresh (Kanthak and Drysdale), 98.

**Squire, F. R.**—Presentation to, 950.

**Stainer, J. W.—Our Weights and Measures, 702.

**Staining Micro-organisms in the Blood (Vincent), 73.

**Stamp Collecting and Disease (Unza), 955.**

**Standards of Purity (Editorial Remarks on), 341; (Beran and Dyer), 413.

**Stapf, Dr.**—Filocarpus Microphylus, 438.

- Dr. Withighbaida Firma, 435.

**Starch as a Mountant (Ballock), 1069.

**Determination of (Stone), 543; (Hibbard), 646.**

- in Compressed Yeast, Determination of (Filinger), 910.

**Pase Cold, The Action of Diastases on (Brown and Morris), 680.**

- Testing for, with Iodine (Meincke), 110.

VOLUME LV. (THIRD SERIES, VOLUME XXV.)—JULY 7, 1894.

FLUORESCENCE OR PHOSPHORESCENCE, AND PHOTOGRAPHIC ACTION AT LOW TEMPERATURES.

Continued investigation of the properties of matter at extremely low temperatures has resulted in a considerable addition to our stock of knowledge on this subject, more especially in regard to phosphorescence and photographic action, and at a special meeting of the Chemical Society, held at the Royal Institution on Thursday, June 28, Professor Dewar, LL.D., described and illustrated in a most brilliant and successful manner his recent observations in that direction. A brief account of the experiments performed on the occasion is here appended, prefaced by a general statement of what was previously known of the phenomena chiefly considered by the lecturer.

NATURE OF FLUORESCENCE OR PHOSPHORESCENCE.

Fluorescence and phosphorescence are terms applied to similar phenomena, which apparently differ in degree only, the first being practically an instantaneous effect, whilst the other lasts for a measurable time. Familiar examples of fluorescence are seen in solutions of quinine sulphate acidulated with sulphuric acid, and some specimens of paraffin oil; and Stokes has shown that the circular surface appearances observed in these liquids are due to a change of refrangibility of the light absorbed, and again given off, by their upper layers. "In every case the fluorescent light appears to belong to a less refrangible part of the spectrum than does the incident light which gave rise to it, thus affording an instance of dissipation, or degradation, of energy" (Tait on "Light"). The duration of fluorescence is very brief, and in this respect alone does it appear to differ from phosphorescence, which, as already stated, lasts for a measurable time.

Phosphorescence, therefore, may be regarded as "merely a species of fluorescence which lasts for a much longer time after the excitation has ceased," and, briefly defined, is the phenomenon observed when certain substances give out light (usually in an altered form) that has been previously absorbed. In this, the most correct, sense of the term it must not be confused with the luminosity due to the slow oxidation of phosphorus, the acid vapours from which shine in the dark with a faint bluish light; nor with the "phosphorescent" appearance accompanying the slow combustion of decaying animal and vegetable matter; nor with the more or less voluntary display of light by fire-flies, glow-worms, and small marine animals.

PHOSPHORESCENT OR FLUORESCENT BODIES.

The substances in which true phosphorescence was first observed were barium sulphide (Bologna stone) and calcium chloride (Homburg's phosphorus), during the seventeenth century, calcium sulphide (Canton's phosphorus) in 1788, and, later, strontium sulphide. When carefully preserved from the air, in sealed glass tubes, these compounds appear brilliantly luminous in a dark room, after exposure to bright sunlight, and for a long time present the general aspect of cooling bodies.

The list of truly phosphorescent bodies has been greatly extended, however, and knowledge of their peculiarities in this direction increased, as the result of investigations instituted by Professor Dewar, in connection with his work on the liquefaction of gases and observations of the properties of substances at extremely low temperatures. Thus, he was able to demonstrate before the Chemical Society that oxygen is itself fluorescent. On passing a stream of this gas or air, after being electrically stimulated, through a very large vacuum tube highly exhausted, a comet-like globe of phosphorescent light was visible, and ozone was formed in the tube, apparently indicating that some kind of molecular change had occurred. It is essential that the air employed should be filtered, as any considerable proportion of organic matter destroys the fluorescence, and the length of the luminous brush formed is inversely proportional to the amount of such impurity present. Even the dispersion of a little ether or perfume in the room may render the experiment impossible for hours. Hydrogen also destroys the fluorescence. The phenomenon is only produced by gases containing oxygen, being shown to a slight extent by carbon dioxide. In the case of calcium sulphide which, after exposure to electric or magnesium light, is highly luminous, cooling by contact with solid carbon dioxide diminishes the phosphorescence, and it is entirely suspended at -80°, though subsequently warming restores the light.

ELASTICITY AS MODIFIED AT LOW TEMPERATURES.

A number of experiments were performed to illustrate the nature of the work which had led up to the results obtained in regard to phosphorescence. Thus, the highly selective character of the oxygen spectrum was shown when a tube containing liquid oxygen was placed in the spectroscope, the dark bands being very distinctly visible in the spectrum thrown upon a screen. Experiments were also performed which illustrated the modification in elastic properties in bodies cooled to low temperatures, the breaking strain of metals,
experiments, however, to measure the relative brightness of the phosphorescence of bodies belonging to definite series.

Remarkable results were obtained with an egg and a feather respectively. The egg shone brilliantly as a globe of blue light, and the feather was equally brilliant, its outline showing clearly in the darkened room. Other organic substances giving good results were cotton-wool, paper, leather, linen, tortoise-shell, and sponge, all phosphorescing brightly, as did also a white flower, apparently cultivated species of Dianthus. Coloured glasses and papers as a rule exhibit no phosphorescence, and when the alcohols are coloured by the addition of a trace of iodine, the luminous effect is destroyed. Milk was shown to be highly phosphorescent and much brighter than water.

Metals also phosphoresce, but in this case the action is due to some organic film deposited from the air, because it disappears on ignition. If the metal is subsequently touched the phosphorescence re-appears. The crowning experiment was performed with ordinary albumin. This is one of the most difficult bodies to cool properly, on account of its tendency to expand and break the tubes. It was shown, however, to possess greater phosphorescing power than the yolk of egg, white bodies generally being superior in this respect to coloured ones, and on cooling a layer on the outside of a test-tube and exposing it to light passing through a quartz lens, it exhibited a brilliancy that was great in the extreme. The difference in luminosity when glass intervened was due, of course, to the fact that glass is somewhat opaque to the violet and ultra-violet rays, the latter of which are most necessary to stimulate bodies and so induce phosphorescence.

Caustic soda and many salts not normally phosphorescent were markedly so at low temperatures. The chloro-, bromo-, iodo-, sulpho-, and nitro-substituted bodies, as a rule, show nothing, or are but faintly luminous. Amongst basic bodies nicotine is more luminous than quinoline or pyridine.

Possible Outcome of the Work.

The suggestion has been made that, as an outcome of these experiments, some connection may be shown to exist between phosphorescence and the structure of matter, and already Professor Dewar has reason to believe that bodies may be naturally classified according to their luminous power at low temperatures. As a provisional generalisation it may be considered that, the greater the complexity of structure in a body, the more likely is it to phosphoresce; on account probably of the increased facility with which its structure enables it to take up the light vibrations. The idea also suggests itself that the luminosity of some of the heavenly bodies may be due to phosphorescence at extremely low temperatures. However this may be, there seems to be a decided probability of fresh light being thrown on the constitution of matter, by the researches now being carried on in the former workshop of the illustrious Faraday, by his distinguished successor, and everyone interested in the progress of physical and chemical science will wait with interest for further developments.
Oxford and its University.

(Continued from Vol. xxiv., p. 1092.)

THE UNIVERSITY AND ITS COLLEGES.

The establishment of universities throughout Europe seems to have been the result of a studious spirit engendered by contact of the western nations with the more cultured people of the East, during the time of the Crusades. Wandering teachers, desiring to spread the knowledge they had acquired, gathered together at chosen centres and lectured to thousands of eager young scholars, drawn from all parts. Schools that had been established for many years, at Oxford and elsewhere, were thus revived, and the outcome was so remarkable as to lead to this period being termed the Medieval Renaissance. As a result of this intellectual revival, at the beginning of the thirteenth century, Oxford was univalved as an English educational centre, and took place in the front rank of European schools.

According to Goldwin Smith and the late Professor Freeman, the University of Oxford was born in the twelfth century, fully a century before the foundation of the first college. The teachers formed themselves into a guild, of which undergraduates were regarded as apprentices, and the degree was originally a licence to teach, carrying with it also the duty of teaching. A charter was obtained by the University, a Chancellor was elected, the graduates—forming an academical Legislature—obtained jurisdiction over the members of the body corporate, and, in time, the teachers and students were marshalled into regular Faculties. At first the professors taught where they could, and the students were mostly poor. They lodged with the citizens, as "chamberdelyns," but were afterwards gathered into hostels or halls (aulae) where they were boarded and governed by Principals or Masters of the University. Some of these halls later became colleges, and as yet remain are similar to the colleges, except that they are not corporate bodies, and possess no fellowships.

The first college to be founded was Merton, in 1264, though University and Balliol are usually dated earlier in deference to the priority of the benefactions out of which they grew. Walter de Merton, the first Founder, was a sometime Chancellor of Henry III., and his College became the pattern for University, Balliol, Exeter, Oriel, and Queen's, at Oxford, as well as for certain colleges at Cambridge. University College, the proper corporate style of which is the Great Hall of the University, claims Alfred the Great as its founder, and in 1872 celebrated its alleged thousandth anniversary. Originally, however, it was only a "hall" where divinity students were lodged, William of Durham having left the University a sum of money for their maintenance, and its first statutes date from 1280. Balliol College was founded by Sir John de Balliol, father of the Scottish king of that name, about 1268; Oriel by Adam de Brume, a court almoner; Exeter by a political bishop of the diocese of that name, Walter de Stapleton, who was killed in a London insurrection; Queen's by Robert de Eglesfield, court chaplain to Queen Philippa. New College was the work of William of Wykeham, Bishop of Winchester, . . . prelate, statesman, and court architect in one, who negotiated the peace of Brestigny and built Windsor Castle." Lincoln, All Souls', Magdalen, and Brasenose were founded in the interval between the foundation of New College and the Reformation, and Corpus Christi towards the end of the same period. The Founder of Magdalen was Waynflete, Bishop of Winchester and Chancellor of Henry VI., another statesman-prelate. This college is distinguished by "the most beautiful of towers." Of all the houses of learning in England, perhaps of any country, that which Waynflete founded is the loveliest, as he will say who stands in its cloistered and ivy-mantled quadrangle, either beneath the light of the summer's sun or that of the winter's moon." Christ Church is the imperfect realisation of Wolesey's conception of an institution where the new learning should be cultivated on a scale of unparalleled magnificence. The tower in which Great Tom hangs, and is tolled every night a hundred and one times for the hundred and one students of the college, was the work of Wren. The church of St. Frideswide's Monastery does duty as the college chapel, and also serves as the cathedral of the diocese of Oxford. Christ Church Hall is described as being—after Westminster Hall—the finest room in England.

Of the remaining colleges, Trinity and St. John's rose from the wreck of other houses; Jesus and Wadham were respectively the first and second distinctly protestant colleges; Pembroke College was founded during the period between the Reformation and the Rebellion, at a time when many of the older foundations were being extended; and the buildings of Worcester include some of the few remaining relics of monastic Oxford. Keble and Hartford are quite modern, the first being founded in memory of the author of "The Christian Year," and remaining as a monument of "Tractarianism;" whilst Hartford, originally Hart Hall, and later Magdalen Hall, is due, as it now stands, to the munificence of Mr. Baring.

In all, there are now connected with Oxford University twenty-one colleges, two halls, three private halls, and two Nonconformist theological institutions—known as Mansfield and Manchester Colleges. These colleges are not affiliated to the University, and do not receive undergraduates in the ordinary way, but are places of theological instruction. Mansfield was erected by the Congregationalists, and Manchester by the Unitarians.

In addition to the undergraduates connected with the different colleges and halls, there are many students who are "unattached," that is, not connected with any such institution. They are under the control of a "Censor," who is a member of a body delegated to maintain discipline, and occupies generally the position of the Head of a College. There are altogether, at the present time, more than twelve thousand members of the University, of whom probably one-fourth are in residence at Oxford, including about two hundred and fifty "unattached" students.

The following are the names of the Colleges and Halls, arranged according to the reputed dates of
their foundation, and with the number of undergraduates connected with them stated:—

The constitution of the University of Oxford has been aptly compared to that of the United States, since it is a federation of self-governing Colleges. The nominal head is the Chancellor, usually a political leader, the present Chancellor being the Marquis of Salisbury, E.G. The acting chief, however, is the Vice-Chancellor, who is selected from the Heads of Colleges, and the present Vice-Chancellor is Dr. Boyd, Principal of Hertford College.

Some time after the Reformation great changes took place in the University as originally constituted, for, resembling others in this respect, it became a place of general education rather than a mart of available knowledge, and its advantages were secured by the rich instead of the poor for whom they were intended by the Founders. The colleges had absorbed most of the halls; the system of college instruction gradually replaced the lectures of University professors; “the College Statutes became more and more collectively the law of the University,” and the Heads of Colleges became the governors of the University, forming a Board called the Hebdomadal Council.

Other changes have occurred from time to time, however, and the University Legislature now consists of an elective Council of Heads of Colleges, professors, and Masters of Arts; the Congregation of residents, mostly teachers; and the Convocation of all Masters of Arts of the University. Legislation is initiated by the Council, and subsequently has to pass the other two houses. Each College, also, possesses its own governing body, consisting of a Head (President, Master, Principal, Provost, or Warden) and Fellows, and has also a private staff of tutors.

*To be continued.*

“**A MAGNIFICENT ENDOWMENT.**”

Under this heading the Times of Tuesday gives an article from which the following details are taken:—

A proposal was made, so far back as 1843, for establishing at the Royal Institution a school for instruction and research in chemistry. It was strongly approved by Professors Faraday and Brande, but, unfortunately, the space at the disposal of the managers was too limited to permit of the scheme being carried into effect. Shortly afterwards the Royal College of Chemistry was founded for teaching the science practically, and numerous schools have since been established for the same purpose, but no adequate provision has up to the present time been made for carrying on systematic research work.

This want is now to be supplied, however, and in connection with the place where it was originally suggested, for at the general monthly meeting of the Royal Institution, on Monday last, the managers announced their acceptance of a munificent offer by Dr. Ludwig Mond, F.R.S., of the great chemical manufacturing firm of “Brunner, Mond and Co.”

Dr. Mond, having purchased the freehold house, No. 20, Albemarle Street, has resolved to convey it in fee simple to the Royal Institution, the buildings of which it adjoins. In addition, he intends to defray the whole expense of converting it into a laboratory adapted for chemical and physical research, and equipping it with everything needful for conducting these upon a large scale. It is to be styled the “Davy-Faraday Research Laboratory,” and will also be endowed by its munificent founder with an income sufficient to defray all expenses of maintenance, etc., as well as the salaries and incidental expenses of a trained scientific staff, so that the work may be carried on in an adequate and business-like manner. No one can fail to appreciate the peculiar appropriateness of this unexampled return to science of that which has been gained by its aid.

A managing committee will be nominated by the managers of the Royal Institution, and Dr. Mond has expressed the desire that the resident professor should accept the position of Director of the new laboratory. This is to be free to individuals of either sex and any nationality, and the sole condition of admittance will be that the persons shall be, in the opinion of the managers, fully qualified to undertake scientific investigation, preference being given to those who have already done original work.

In thus realizing the idea of half a century ago, Dr. Mond is also providing additional accommodation for the existing Institution, since it will now be possible to extend the library and the present chemical laboratory. His conclusion that the new laboratory would have the greatest prospect of success if connected with the Institution which has always fostered research, will commend itself to all who have realized the importance of the results attained by the illustrious investigators who have worked there from its foundation to the present time. Dr. Mond hopes that others may found scholarships and bursaries to enable promising students without means to avail themselves of the opportunities now offered, and this suggestion deserves the fullest consideration.
The Pharmaceutical Journal
FIFTY-FOURTH YEAR OF PUBLICATION.

SATURDAY, JULY 7, 1894.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, Bloomsbury Square, London, W.C.
Instructions from Members, Associates, and Students, respecting the transmission of the Journal, should be sent to MR. RICHARD BREMBIDGE, Secretary, 16, Bloomsbury Square, London, W.C.

Advertisements and remittances must be sent to the Office of the PHARMACEUTICAL JOURNAL, 6, Serle Street, Lincoln's Inn, London, W.C., where Copies of the Journal may be Purchased. Cheques and Money Orders should be made payable to "STREET BROTHERS."

THE COUNCIL MEETING.

At the meeting last Wednesday, after the reading and confirmation of the minutes of the previous meeting, the PRESIDENT announced that Mr. J. LAIDLAW EWING had been re-elected Chairman of the Executive of the North British Branch of the Society, and that Mr. CHARLES KERR has been elected Vice-Chairman.

Letters from Professors REMINGTON and RUSBY and Dr. G. WATT, acknowledging the honour conferred by their appointment as honorary and corresponding members of the Pharmaceutical Society, were read by the PRESIDENT, who also mentioned that Mr. CARR had been nominated by the Research Committee for the Salters' Scholarship.

The business arising out of the reports of the Finance, Benevolent Fund, and Library, etc., Committees was mainly of a routine character. The VICE-PRESIDENT referred to a visit he had paid, with Mr. WALTER HILLS and the Secretary, to the Watford Orphan Asylum, speaking in high terms of the conditions under which the inmates are placed in that institution.

The announcement that Mr. WALTER HILLS has accepted the invitation of the Library, etc., Committee to deliver the inaugural sessional address at the opening of the Society's School in October was received with much satisfaction.

In response to an application from the local Chemists' Association at Plymouth for a materia medica cabinet, the recommendation of the Committee that a grant of twenty pounds should be made was adopted.

The appointment of the staff of the School of Pharmacy and of delegates to the British Pharmaceutical Conference was then proceeded with.

Mr. MARTINDALE, in proceeding with the motion standing in his name upon the agenda, reviewed the action taken by the Society in regard to the metric system of weights and measures, contending also for the desirability of its adoption in dispensing, and that such a step would not be attended with any real difficulties. His own experience as an examiner had shown him that candidates had little practical knowledge of the metric system. He disapproved of the attempts which have been made to introduce it partially, and he had therefore brought forward his motion in order to have the question thoroughly discussed, since this country and India were the only exceptions to the adoption of the metric system. He referred to the result of the discussion at the International Congress at Chicago, and hoped his motion would receive from Mr. MARTIN the same support that he had given to the resolution then passed, as to the desirability of the metric system being the only system of weights and measures used in a pharmacopoeia.

Mr. RYMER YOUNG, in seconding the motion, expressed the opinion that it was most important pharmacists should feel as confident in dealing with prescriptions written in the metric system as with others. The objection that mistakes might arise from misuse of the decimal point applied equally to the present system, and he thought the adoption of the metric system might have the effect of inducing medical men to write prescriptions more legibly.

The PRESIDENT here interposed to ask speakers to confine their attention to the terms of the motion, and he suggested that the question whether the introduction of the metric system into the British Pharmacopoeia is desirable was really outside the motion. Mr. MARTIN, agreeing generally with that view, thought the subject would be a good one for discussion at an evening meeting, but until Parliament decides upon adopting the metric system, and the Medical Council authorizes its use, it would be an unnecessary complication of the examinations to follow Mr. MARTINDALE's suggestion. Mr. HILLS partly supported the motion, but thought an alteration of its form would be advisable, though pharmacists should be in advance rather than mere followers of the Medical Council in regard to any system they felt ought to be adopted, especially in the case of a reform likely to be introduced before long. Mr. ALLEN said he had expected to hear arguments in favour of the motion; but he did not believe in the existence of such ignorance of the metric system as had been suggested, and, as he thought the average chemist's assistant would be able in a few months to become thoroughly familiar with its use, he did not see any reason for examining candidates for the qualifying examination upon the metric system until it had been adopted by medical authorities. Mr. HAMPSHIRE supported the motion on the ground that extended use of the metric system is desirable.

The PRESIDENT pointed out that the Council, having no authority to make regulations for the Board of Examiners, that was not the place to discuss the question raised. The difficulties that would be created by examining in two systems of
weights and measures would embarrass candidates as well as examiners. He thought Mr. Martindale's motion went too far, and suggested that if its principle were adopted, it should be sent as a recommendation to the Board of Examiners to consider. Mr. Bottles supported this view, while acknowledging the value of acquaintance with the metric system, and hoping that before long it would be introduced into the British Pharmacopoeia. Mr. Atkins considered that some of the points touched upon might be disregarded as appertaining to a academic discussion. If there was any inconsistency between the requirements of the two examinations that matter was worthy of consideration by the Board of Examiners, and Mr. Schacht said that in voting on the motion he should be guided by his view as to its aim being to enable young men to prove their ability to dispense by one system as well as the other.

Eventually at the suggestion of the President, Mr. Martindale agreed to alter the wording of his motion so as to reflect the views of the Council, and it was carried as a request that the Board of Examiners should consider the subject.

A letter from the Colonial Office asking for any comments the Council might have to make on a law passed by the Legislature of Jamaica for regulating the sale of poison was referred to a committee for consideration. The President read a letter from Mr. FitzHugh, President of the Nottingham and Notts Chemists' Association, enclosing a resolution expressing approval of the draft Pharmacy Bill, and stating that the Association is prepared to support the Council in the endeavour to get it passed.

The report of the General Purposes Committee gave the results of cases in the hands of the solicitors, and on the recommendation of the Committee, proceedings were ordered to be taken in a number of other instances of infringement of the Pharmacy Acts.

The President reminded the Council that since the last meeting Mr. Savage, a former member of the Council and Vice-President, had died, and with the desire of paying a tribute to his memory he asked the Council to authorise him to write on its behalf, expressing to his widow the sincere regret felt at his decease. The proposition was supported by Mr. Atkins, in terms expressing high appreciation of Mr. Savage's character and interest in the Society, and was unanimously agreed to.

ENDOWMENT OF RESEARCH.

With the object of promoting the prosecution of chemical and physical research, a very munificent presentation has been made to the Royal Institution by Dr. Ludwig Mond, one of the partners in the firm which has successfully established in this country the manufacture of alkali by what is termed the ammonia process. We have abstracted from the report which appeared in the Times of Tuesday last a general statement of the details of Dr. Mond's gift (see page 4), from which it will be seen that provision is made for giving practical effect to an aspiration long since entertained by Faraday, but not hitherto practically realisable.

For the information of our readers it may be desirable to state that Dr. Mond is a native of Cassel, in Germany, and that he received his scientific education in that country as a pupil of Kolbe and Bunsen. Having early directed his attention to the scientific development of manufacturing industry, he was successful in devising an important method of usefully recovering from the waste of alkali works the sulphur it contained, and in carrying out that process he came to England in 1862, where he has since chiefly resided. In 1873 Dr. Mond founded the ammonia soda works of Messrs. Brunner, Mond and Co., at Winnington, Cheshire, now the property of a limited liability company, of which he is still managing director.

Besides occupying this important position as a manufacturing chemist, Dr. Mond has always been an enthusiastic investigator, and has in that capacity not only made numerous improvements in the details of the ammonia soda manufacture, and the production of chlorine as a bye-product, but has also devised processes for the manufacture of cyanides, peroxides, the production of ammonia from coal, of hydrogen, and electrical gas batteries. His discovery of a very interesting compound of nickel with carbonic oxide has also furnished means of extracting nickel from its ores and applying it to various useful purposes.

In addition to holding the German scientific degree of Ph.D., Dr. Mond is a fellow of the Royal Society, a Vice-President of the Royal Institution and of the Chemical Society, as well as a past President of the Society of Chemical Industry.

In connection with the advance of chemical science and its application to manufacturing industry, it may be mentioned that this country is already deeply indebted to Germany. It is no less indebted to individual Germans who have assisted in carrying out such applications, and also in establishing systematic scientific education in chemistry. Reference to the names of A. W. von Hofmann and C. W. Siemens will sufficiently support that statement, and the provision now made by Dr. Mond for organising means of conducting scientific research adds another striking illustration of the fact. Though in no way detracting from the value of the services thus rendered, it is almost humiliating to be compelled to acknowledge that they altogether eclipse any similar attempts on the part of the Government of
this country, or of native representatives of manufacturing industry. A perception of the fact that advanced scientific knowledge is the mainspring of industrial progress has yet to be gained by the majority of the British people. In Germany that fact has long been recognised, and while that country is reaping the fruits of a century’s laborious cultivation of chemistry and its promotion by the State, investigation in that as well as other departments of science is still conducted in this country, as of old, more as the pastime of the wealthy than as a national necessity. To the alteration of that condition Dr. Mond’s munificent action will contribute largely, and as following up the work of his countryman Hofmann, it may be expected to produce results which will command the grateful appreciation of all British subjects.

BRITISH PHARMACEUTICAL CONFERENCE.

The programme of the thirty-first annual meeting of the British Pharmaceutical Conference, to be held at Oxford, under the presidency of Mr. N. H. Martin, of Newcastle-on-Tyne, has now been finally arranged and approved by the Executive Committee. On Monday, July 30, there will be a reception by the President and a conversation in Christ Church Hall, by kind permission of the governing body, at 8.30 p.m. An exhibition of scientific instruments, etc., will be supplemented by music and light refreshments. On Tuesday, July 31, at 10 a.m., the Sessions of Conference will be opened in the Hall of Balliol College, by kind permission of the Master and Fellows. After an official welcome by the Mayor (Walter Gray, Esq.) the presidential address will be delivered, and followed by the reading and discussion of papers. At 1 p.m. luncheon will be served at the Randolph Hotel, the Conference headquarters, and at 2 p.m. the Sessions of Conference will be resumed. A garden party will be held in the grounds of New College, by kind permission of the Warden and Fellows, at 4.30 p.m. the same day, and afternoon tea will be served there. On Wednesday, August 1, the business proceedings will follow the same course as on the previous day, the Sessions of Conference being resumed for the last time at 2 p.m., and at 4.15 p.m. visits will be paid to various colleges, the city, etc. Subsequently, the usual smoking concert will be held at the Randolph Hotel, at 9 p.m. On Thursday, August 2, the last day of the Conference, there will be a river excursion to Abingdon, starting from Folly Bridge at 9 a.m. Luncheon will be prepared in the Council Chamber, Abingdon, by kind permission of the Mayor (E. Morland, Esq.), at 1.30 p.m., and at 3 p.m. the boats will leave Abingdon. The members will be able to visit Nuneham Park, the seat of Aubrey Harecourt, Esq., on the return journey, and at 5 p.m. tea will be ready on board the boats. The arrival at Oxford is expected to take place about 8 p.m. The books of tickets may be obtained of Mr. Henry Mathews, the Honorary Local Secretary, 108, High Street, Oxford, to whom application should be made not later than July 23. Hotel accommodation will also be arranged for by Mr. Mathews, if early intimation be sent to him of what is required in that respect. As a trustworthy and up to date handbook for visitors ‘Alden’s Oxford Guide’ is specially recommended by the local committee.

DOCTORS IN SCIENCE.

Amongst those admitted to the honorary degree of Doctor in Science at Cambridge, on Wednesday, June 27, we omitted last week to record the name of an honorary member of the Pharmaceutical Society, in the person of Professor Dimitri Ivanovitch Mendeleeff, late of the University of St. Petersburg. The speech delivered on the occasion by the Public Orator (Dr. Sandys) was as follows:

“...In scientia chemica investiganda dita inter peritos quæsebatur, quænam ratio interest inter atomorum pondera et quibus rerum elementa constarent et vires eae, sive chemicas sive physicas, quæ elementis ipsis velut propriæs inhaerarent. Qua in ratione peneorum perscrutanda atque ad certam quandam legem redigenda nemo plura perfecter eximiamur quam vir illustri qui Sibiriæ in remote natura, et undeque abhinc annos societate regia Londinensi nominatum auro donatus, hodie nostra corona qualcumque deunatur. Magnum profecto est inter tot elementa rationem certa intervallis velut circuitu quoddam recurrentem observasse, equo rerum notarum observantio etiam ignota provideisse. Viri huius ingenio etiam elementa prius insedita metalls divinitatione singulari praedicta sunt postceca in ipsa rerum natura reperta. Quae elementa, trium gentium nominibus Gallurn, Scandum, Germaniam nonomnepa nomen ipsius illustrius reddiderunt et Russorum famam, quantum ad ipsum attinet, feliciter aevurnent. Ergo virum de scientia chemica tamen tamque præclarum maritum, totque titulis adlescit, hodie etiam nostrorum ‘farba Quantitatem tollere honoribus.’

Newtoni certe in Academia honos ei præsertim, debetor, qui etiam in scientia chemico Newtoni in vestigiiis tam fideliter insistit, ut alium nostris qui genus humanum ingenio superavit imaginem intueri, Lucreti verbs paululum mutata possit usurpare:—

‘Te sequor, o Grattaei magnus deonis, inque tuis nunc Flecta pedum pono prexis vestigia signis.’”

We note also that a grant of the Senate of the University of Dublin has been passed, conferring the degree of Doctor in Science upon Mr. Daniel Morris, C.M.G., Assistant-Director of the Royal Gardens, Kew.
Transactions of the Pharmaceutical Society of Great Britain.

MEETING OF THE COUNCIL.

Wednesday, July 4, 1894.

Present—

MR. MICHAEL CARTWRIGHT, PRESIDENT, 
MR. WM. GOWEN CROSSE, VICE-PRESIDENT, 
Messrs. Allen, Atkina, Bottle, Grenchin, Gosling, 
Hampson, Hills, Martin, Martindale, Schacht, Southall, and Young.

The minutes of the previous meeting were read and confirmed.

THE INTERNATIONAL CONGRESS OF HYGIENE.
The President moved the appointment of Dr. B. H. Paul as delegate of the Pharmaceutical Society to the International Congress of Hygiene at Buda Pesth. This was seconded by Mr. Hampson, and carried unanimously.

THE NORTH BRITISH BRANCH.
The President said a notification had been received from the Assistant Secretary, Mr. Rutherford Hill, that Mr. J. Leidlaw Ewing had been elected Chairman and Mr. Charles Kerr, Vice-Chairman of the Executive for the ensuing year.

HONORARY AND CORRESPONDING MEMBERS.
The President read a letter from Professor Remington thanking the Society for the honour conferred upon him in electing him an honorary member.

He also read letters from Professor Rusby and Dr. George Watt, thanking the Society for their election as corresponding members.

THE SALTSER SCHOLARSHIP.
The President announced that the Research Committee at a meeting on the preceding day had unanimously nominated Mr. F. H. Carr as Salters' Fellow for the ensuing year. His election would be made by the Court of the Salters' Company in October next. He might mention that Mr. Carr had been selected out of a number of gentlemen with very high qualifications, after very full consideration.

ELECTION OF A MEMBER.
The following, who was in business before August 1, 1898, having tendered the subscription for the current year, was elected a "Member" of the Society:

Lloyd, George Henry

Wolverhampton.

ELECTION OF ASSOCIATES IN BUSINESS.
The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:

Blore, George James

Pendleton.

Huggins, Samuel

Barnet.

Raffan, John

Stirling.

Wright, George Victor

Ayr.

ELECTION OF ASSOCIATES.
The following, having passed the Minor examination, and tendered their subscriptions for the current year, were elected "Associates" of the Society:

Donald, James

Newcastle.

Gillitt, Albert Ambrose

The Assistant, London.

Robertson, Joseph

Aberdeen.

ELECTION OF STUDENTS.
The following, having passed the First examination, and tendered their subscriptions for the current year, were elected "Students" of the Society:

Andrew, John Reginald

London.

Bryant, Nicholas J. Andrew

Truro.

Burge, William George

St. John's Wood.

Burgess, Sydney Robert

Luton.

Green, George Turton

Stourbridge.

Hodgson, Baron Guthbert

Halifax.

Hughes, Richard Owen

Blanesk Festingoth.

Jones, Driver Fisherbert

Devizes.

Jutton, Sidney Arthur

Margate.

Kable, Martin Anton Gotfried

London.

Martlew, Charles

Carlisle.

Miller, Thomas

Berwick-on-Tweed.

Mitchell, Henry Searle

Truro.

Morray, George

Market Drayton.

Reckhams, Walter (jun.)

Sheffield.

Robinson, Edward George

Lincoln.

Swanson, Alex. J. Robertson

Edinburgh.

Topping, Edmund

Bury.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a nominal restoration fee of one shilling.

RESTORATION TO THE REGISTER.
The name of the following person was restored to the Register of Chemist and Druggists:

Jonathan Boor, 62, Denmark Road, Manchester.

REPORT OF THE FINANCE COMMITTEE.
This report was of the usual character, and recommended sundry accounts for payment.

The President (as Chairman of the Committee) moved the adoption of the report, saying its special feature was the receipts from an unusually large number of candidates. On the Benevolent Fund account they had received but very few subscriptions, and as to the latter items nothing was to be added to the report of the Registrar.

The adoption of the report was seconded and carried.

REPORT OF THE BENEFICIAL FUND COMMITTEE.
The report of this Committee included recommendations of the following grants:

£12 to the widow (55) of an Associate who died in 1878. In 1874 she had paid a grant of £10 to assist in educating her children, five of whom are living, two daughters being at home, one consumptive. (Hastings.)

£5 to the widow (68) of a chemist and druggist, who had a grant of £5 in 1883 and £5 in 1891. (Sheffield.)

£10 to a former member (75) and a subscriber to the Benevolent Fund. Applicant has had five previous grants, amounting to £26, the last in 1893. (Hull.)

£7 to a registered chemist and druggist (80) and former subscriber to the Fund. Applicant has had four previous grants, amounting to £26. (Lynn.)

One case was deferred, and two were not entertained.

The Vice-President (as Chairman of the Committee) then moved the adoption of the report, which he said, called for no special comment, but he should like to say a word with regard to the Orphan Fund. During the last month Mr. Hills and the Secretary went with him to the Watford Orphan Asylum to see the orphan who had been placed in that institution through the instrumentality of the Fund. They were met with every consideration and cordiality, and the general arrangements of the establishment struck them as being everything that could be desired. The cleanliness and order which prevailed throughout were very noticeable, and in themselves formed a most valuable portion of the education which the children received. The little boy was very glad to see them, and seemed to be very happy. An interesting fact which they
ascertained was that it was only through an institution or society that orphans could be received in that establishment by annual payments; a private individual must pay a lump sum to secure the entrance of an orphan. He hoped they would not have many orphans to provide for, but he was very pleased to feel that when such cases did occur they were able to give a thoroughly good start in life to those who were left unprovided for.

Mr. Hills said he concurred in what the Vice-President had said as to the pleasure with which he and his colleagues regarded the arrangements of the institution, and the care evidently bestowed on the orphans.

Mr. Hampson added a few words, and the report was adopted.

REPORT OF THE LIBRARY, MUSEUM, SCHOOL, AND HOUSE COMMITTEE.

Museum.
The Curator's report had been received, and included the following particulars:—

<table>
<thead>
<tr>
<th>Attendance</th>
<th>Total</th>
<th>Highest</th>
<th>Lowest</th>
<th>Average</th>
</tr>
</thead>
<tbody>
<tr>

Circulation of Books—

| May | 244 | 139 | 105 | £1 6s. 4d. |

Donations to the Library had been announced (Pharm. Journ., June 16, p. 1059), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The staff of the Society's school had attended, and reported on the various classes.

As application from the Three Towns and Plymouth District Chemists' Association for a materia medica cabinet was considered, and the Committee recommended that a sum of £20 be granted under the power they had adopted in the case of Chester in February, 1892.

The President was requested to invite Mr. Walter Hills to deliver the Inaugural Sessional Address in October next.

The President, in moving the adoption of the report, said he noted the pleasure with which the members had received the reference to Mr. Hills, and he was glad to be able to add that Mr. Hills had consented to deliver the address.

The report was unanimously agreed to.

APPOINTMENT OF SCHOOL STAFF.

Professor Atfield was re-appointed Professor of Practical Chemistry; Professor Dunstan, Professor of Chemistry; Professor Green, Professor of Botany; Professor Greenhal, Professor of Pharmacy; and Mr. Joseph Ince, Lecturer in Pharmacy, for the ensuing session.

METRICAL WEIGHTS AND MEASURES.

Mr. Martindale moved:—

"That after the first day of January, 1895, a practical knowledge of the metric system of weights and measures shall be required of all candidates for the Minor Examination in the subjects of Pre-
scriptions and Practical Dispensing, and that the Boards of Examiners be instructed to require from candidates 'a general knowledge of Posology in terms of the metric as well as the British system of weights and measures, as defined by the British Pharmacopoeia, 1885,' and in Practical Dispensing 'to weigh, measure, and compound by the metric system as well as by the British system of weights and measures.'"

He sketched the history of the Society's action in regard to the metric system of weights and measures, saying that although there was some talk of adopting it twenty-eight years ago, it was not made a subject for examination till 1893. In the regulations required for the Minor Examination, the alterations and new regulations then introduced requiring that candidates in pharmacy should possess a practical knowledge of the metric system. A year or two afterwards the examinations were conducted on this system, but it was carried out only in a limited way, and his experience at the time was that candidates possessed very little practical, as distinguished from theoretical, knowledge of the subject. In 1872, and again in 1874, there were other revisions of their examination requirements, and he suggested a practical examination in dispensing measures under the system. In the President and others taboed the proposal. However, in 1874, the metric system was transferred to the First Examination, and in the schedule for that year, candidates were required to have a thorough knowledge of the system. He had then pointed out that this "thorough knowledge" proved to be of a superficial kind, and he urged that it should be more practical. The next alteration was in the regulations of 1891, and the subject was still retained. In chemistry and physics, he showed by quoting the regulations, that candidates were expected to possess an elementary knowledge of the metric system of weights and measures; but he thought that something more than elementary knowledge was required when, except in our own country and its dependencies, almost every civilised nation had adopted it. Moreover, he found that the knowledge we required was of a very dictatorial and not of a practical kind. He was aware that when abolition had been carried out in the United States, and almost every other country except India and our own has adopted the system, it was time we also recognised and carried it into practice. It had been proved to be the most symmetrical and simple in determining minute quantities accurately. Quantities by volume were much more significant, especially small quantities, which easily conversed into one another, which was not the case with the weights and measures of the British Pharmacopoeia. The two smallest denominations were the minims and the grain, and in weight there were but three measures—the grain, the ounce, and the pound. But the dose of morphine was from 1/2 to 2 grains, of strychnine 1/8 to 1/4 grain, and of arsenic 1/16 to 1/8 grain, so that there were no weights small enough to weigh a single dose. Again, the grain was not an aliquot part of an ounce, and you could not use the avoidrupo ounce for many purposes, because it took 457.8 grains to make the ounce, and you were almost obliged to use the obsolete troy ounce of 480 grains for dispensing purposes. This system seemed too absurd to be continued; it was as if in coinage there were nothing between a penny and a pound, and the pound did not contain a certain number of pence. What were the objections to be introduced into the metric system? It was said that it would cause confusion and lead to mistakes. But on whose part? Was it on the prescribers? If so, pharmacists, knowing the subject thoroughly, would be able to correct them. Before prescribers took the matter up there would be a long period of transition, in which
both systems would go on simultaneously. But he believed the mistakes which were anticipated would be those committed by pharmacists in dispensing, and it was for this reason he wished the system included in the examinations, so that the students should be thoroughly trained in it, and he also wished to think of it, and recognize unusual doses at once. Until physicians had confidence in pharmacists' knowledge of the metric system they would never prescribe in it. If the system were introduced, it should include both weights and measures, because liquids could be much more accurately measured than weighed. In America the system had been introduced into the last edition of their pharmacopoeia, and he thought it was not creditable to England to be behind in this matter. He much regretted that the editors of the last two editions of the British Pharmacopoeia had not been able to introduce the metric system. He had, therefore, brought forward the motion in order that the question might be thoroughly discussed and thrashed out before a new edition was published. The metric system was almost universally employed elsewhere, and pupils who had learned it elsewhere had told him that on having to learn the English system it seemed barbarous in comparison. The conversion of the pharmacopoeia proportions into parts, either by weight or by volume, had been the subject of discussion by several professors, and various suggestions had been made from time to time, from 1859 downwards. The late Mr. Peter Squire planned a certain number of equivalents, so as to make the conversion from one system into the other easy and practicable. Subsequently, Professor Atfield suggested the introduction of a grain-measure instead of the minim for dispensing, the fluid-grain being the equivalent of the grain weight of distilled water, but that would not have been an aliquot part of the fluid dram or fluid ounce, and rather than adopt that he would prefer things to remain as they were. He should oppose any alteration in the value of the minim or the grain, which were the two most important quantities to pharmacists, and he was sorry to say that their equivalents in the metric system were not easily obtained. No doubt there would be a transition period, of from twenty to thirty years perhaps, in which the old system would continue to be employed, but there need be no difficulty about that. The great point was whether the metric system introduced into the pharmacopoeia was a proper scale of denomination. Twenty or thirty years ago he endeavored to familiarize medical students with the subject, and in revising the University College Hospital Pharmacopoeia in 1873 he put the equivalent doses of medicines in the metric system, and the same plan had since been carried on by Mr. Gerrard. That evening he had received from the President of the American Pharmaceutical Association a letter, in which he enclosed tracings of several prescriptions dispensed in Boston, in some of which metric quantities were named. He noticed that the German system of writing was followed rather than the French, which he thought preferable and more practical. The subject was discussed at the International Pharmaceutical Congress in Chicago, and he hoped Mr. Martin would support his motion to-day, as he had then spoken in favour of the resolution that was passed, to the effect that in the opinion of the Congress the decimal system of measures based on the centimetre as the only unit of measures used in a pharmacopoeia was the fluid measurements employed in the measurement of liquids. Mr. Martin then said that the metric system was in common use in England amongst scientific men, and if certain difficulties were removed no English pharmacist would be opposed to its introduction into the pharmacopoeia. He should be glad to know what the difficulties were other than disinclination, or he might, perhaps, almost call it laziness. There had been many discussions on this subject at evening meetings and elsewhere, but nothing seemed to come of them, and he therefore brought forward this motion in order to see whether or not they should vote for it.

Mr. Young seconded the motion. He said most pharmacists had occasionally continental prescriptions to make up, and it was important that both they and their assistants should feel as confident in dealing with them as with those written in the usual style. Mr. Martindale had drawn attention to the fact that Switzerland had become the only country that clung to an antiquated system; he knew there were many people who revelled in anything antiquated as opposed to anything modern and useful, but he thought the Pharmaceutical Society, which had of late years appeared to have awoken from its Rip Van Winkle-like sleep, should be the last to oppose any scientific reform. It had been objected that mistakes might arise from the misplacement or omission of a decimal point, but there were equal dangers in the present system from confusion between the mark for the ounce and the dram. At any rate, the metric system seemed to exert an influence on the medical profession, which might rise to the necessity of writing legibly and using correct Latin.

The President said he must ask gentlemen to confine their attention to the terms of the motion. He did not like to interrupt the proposer, though a large part of his speech was devoted to matters which would have been very suitable to an evening meeting, but was entirely beside the subject of the motion. The question of whether the introduction of the metric system into the British Pharmacopoeia was desirable was really quite outside the motion. Mr. Martin said he agreed generally with the views of the President. He thought the subject would be a good one for a paper, and more suitable than for a meeting of this kind. The House of Commons, it seemed to him, should first be approached, with a view to the introduction of the metric system into this country. Until the Medical Council had adopted it he did not see how they could reasonably impose it upon candidates in pharmacy. As to the suggestion that the system prevailed so slightly in the pharmacies of the United Kingdom, that fact would seem to show that it was not required. Until it was more or less authoritative adopted in the country, he did not see why they need enforce it further than was now done, though he was not sorry they had had a discussion on a subject of which they would probably hear more rather than less in the future.

Mr. Hiles supported Mr. Martindale to a certain extent, but thought it would perhaps be advisable to alter the form of the motion. Still, he thought they should be in advance rather than mere followers, and not wait for the Medical Council or any other body to introduce a system which they, as pharmacists, felt ought to be adopted. Assuming Mr. Martindale's view as to the requirements in the examinations to be correct, they seemed to him to be somewhat contradictory. However that might be, he considered that as all knowledge was power, they should be well in advance of probable needs, and make such judicious regulations as would be calculated to add to the rate of the time of a reform, which he would not doubt, before many years were past, be adopted in England.

Mr. Allen said he had looked forward to this discussion with considerable interest, expecting to hear some arguments which would enable them to decide whether or not they should vote for the motion. He was not prepared to admit the prava-
lence of such comparative ignorance in respect to the metric system as had been hinted at, and Mr. Martindale's own arguments, he thought, tended to show that the pharmaceutical Society had, down to the present time, shown its appreciation of the position by enforcing on candidates some knowledge of the system. If the difference prevailed between the Preliminary and the Minor Examinations which had been spoken of, he thought a remedy should be provided. He believed, such a belief in the powers of the average young man now coming forward as pharmacists that, apart from the meaning of what was "thorough" knowledge, should the metric system be introduced into the pharmacy, he had no hesitation in believing that a few months only would be required to make the average chemist's assistant throughout the kingdom thoroughly familiar with it. Until the medical authorities had given us a national pharmacy, embracing the metric system, he did not see any reason for examining candidates for the qualifying examination in the system.

Mr. HARRISON supported the motion, and thought that the inclusion of some knowledge of the system was an argument in favour of its extension and making it more practical.

The President said, he, too, was strongly impressed with some of the views which had been advanced, but he desired to brush away a good deal of what had been said. He did not think it possible in a very short time to come to the practical portion of Mr. Martindale's suggestions. He would remind the Council that it had no authority to make regulations for the Board of Examiners, and he doubted whether this was the best place at which to discuss such a question, but he assumed that any recommendation the Council might make would receive every attention from the Board. He took it that the general system of education for the profession was now so cosmopolitan and general that, supposing the introduction of the metric system of weights and measures should be advisable, any ordinary schoolboy of average capacity could be put through the course in a very short time. To those not instructed in the system of grammes and centigrammes he apprehended it would be no easy thing in the throes of an examination to compare them with English weights; but he suspected that a fair majority of those most interested in the subject, and the Society had done more or less practical work in the metric system, and therefore for the purposes to which it would ordinarily be applicable they would know the difference between the two. The point now, as he understood it, was, were they to carry this further and make the metric system somewhat of the nature of a specific subject. For himself, he had no objection to a week being devoted to examination; but if they decided on adopting Mr. Martindale's views, the Board of Examiners would probably ask how it was to be carried out. If the motion were to be accepted the examiners would have to test candidates in the metric system as well as in the traditional system. They might then find it necessary, for want of time, to leave out one of them, and the question was, which of them? These were practical considerations which he thought the Council should anticipate in any decision to which it might come. Then, in the mind of a chemist, he supposed the metric system was already sufficiently searching without making any addition to them. Thinking that Mr. Martindale's motion went too far, he suggested that it would be better, if its principle were adopted, to send it to the Board of Examiners as a recommendation, and not as a system, and prove themselves as well able to dispense under one system as under the other.

Mr. MARTINDALE, to meet the obvious feeling of the Council, expressed his willingness to make his could be practically applied he thought must, after all, come before the body responsible for its administration and application. He protested against the idea that they were to "grow" men for particular mechanical operations; rather what they wanted was all-round educated men, with a capacity for absorbing and working out new ideas such as were embodied in the resolution. The function of the Society was primarily the protection of the public in providing that those who dispensed medicines should understand the subject; a question like that under consideration was entirely subsidiary and secondary to this. As to the argument of the Society being in advance, he did not think Mr. Martindale's motion would have the slightest effect upon the medical profession, whilst from the examination point of view he thought it impracticable, if not unduly adding to the burdens and difficulties of candidates. He spoke as an examiner, and he thought Mr. Martindale would be the first if he had a boy of his own under examination to recognize the justice of the remark, that, the fewer the exams were wanted, the sooner they could be sat by and by degrees; and should the motion be carried, he earnestly counselled its reference to the Board of Examiners.

Mr. Hills suggested that perhaps Mr. Martindale would alter his motion in that respect to meet the President's remarks, in which he thought there was some force.

Mr. BOTTLE spoke in the same spirit. It was not for the Council to initiate regulations for the Board of Examiners, but it might submit its ideas to that body for approval or suggestion, and then, thought, would be a step in the right direction. As practical men, he thought they must acknowledge the metric system contained some points of great advantage, not least among them being its universality on the Continent; and he mentioned a case of a young friend of his, having settled down in a small pharmacy which had been neglected, he had been encouraged and enabled to build up a decent practice through the discovery by two of a large of the beauty of the Continent, that, to their delight and satisfaction, not less than their astonishment, he was able to dispense a prescription in the measures which they placed before him.

The President expressed his opinion that the practical meaning of the word "thorough" in the requirements of the candidates was well understood, as being designed rather to test the candidate's general ideas of a system not generally used in this country than as indicating a very deep knowledge of its possibilities and capacities.

Mr. SCHURR asserted he should be guided in his vote on the question according as he understood that its purpose was to provide for young chemists in one stage proving themselves as well able to dispense under one system as under the other.

Mr. MARTINDALE, to meet the obvious feeling of the Council, expressed his willingness to make his
motion read that the Council suggests the desirability of requiring a practical knowledge, etc.
The President suggested that the practicability or advisability of the course suggested should be referred to the Board of Examiners.
Mr. Martindale said he would word his motion in any form that might be thought most advisable for reflecting the spirit of the Council. It was eventually decided that the motion should read as follows:—"In this form it was put to the meeting, and carried:—

“That the Boards of Examiners be requested to consider the desirability of requiring a practical knowledge of the metric system of weights and measures of all candidates for the Minor Examination.”

It was resolved on the motion of the President that the Board of Examiners be empowered to receive in the case of Mr. J. M. Ricardou the certificate of the University of France, in lieu of the First Examination.

LETTER FROM MR. G. W. SARGENT.

The President read a letter which had been received from Mr. G. W. Sargent, in reply to one sent by the Secretary in pursuance of the resolution of the Council at its last meeting, asking for an explanation of the conduct ascribed to the general manager of the South-Eastern Railway Company at Gravesend, reflecting on the conduct of the Local Secretary for Gravesend. Mr. Sargent said in his letter that as “a chemist, citizen, or insurance agent,” he had a perfect right to draw attention to the “Revels of Explosives, and other Acts.” He moved that the Council consider Mr. Sargent’s reply unsatisfactory, and that two members of the Council be deputed to communicate with him in accordance with the Bye-laws, section XVII, subsection 2, and report to the next meeting of the Council.

This was unanimously agreed to.

THE PHARMACEUTICAL CONFERENCE.

The President, Vice-President, Treasurer, and Messrs. Atkins, Bottke, Goetting, Grose, Hille, Martin, Martindale, Schacht, Southall, and Young were appointed delegates to the British Pharmaceutical Conference meeting at Oxford. The Secretary, Editor, and Sub-Editor were also requested to attend.

THE PHARMACY IN JAMAICA.

The President said a letter had been received from the Colonial Office enclosing a copy of an Act passed by the Legislature in Jamaica for regulating the sale of drugs and poisons, and asking for any observations the Council might have to make upon it. He would move that the letter and enclosure be referred to the Library, Museum, and School Committee for consideration.

This was unanimously agreed to.

THE DRAFT PHARMACY BILL.

The President read a letter which had been received from Mr. FitzHugh, President of the Nottingham and Nottingham Chemists’ Association, enclosing a resolution approving of the draft Pharmacy Bill, and saying that the Association was prepared to support the Council in its efforts to get the Bill passed into law.

GENERAL PURPOSES COMMITTEE.

The report of this Committee, which was as usual read and considered in committee, included a letter from the solicitors with regard to legal cases placed in their hands. A number of fresh cases of infringement of the Pharmacy Acts were reported to the Committee, and proceedings were recommended.

On resuming, the report and recommendations were unanimously adopted, and a special resolution was passed authorising the Registrar to take proceedings against the persons named.

THE LATE MR. SAVAGE.

After the reporters had left, the President said he had unfortunately omitted, before concluding the ordinary proceedings, to pay a tribute to the memory of a past member of the Council for many years, and a former Vice-President of the Council, who was for many years an active pharmacist, and whose whole life was, he might say, gladdened by his association with the Council. He referred to Mr. William Dawson Savage, who had died since their last meeting. As President, he had already sent a card of condolence to his aged widow, and he would ask the authority of the Council to send a letter in its name expressing the sincere regret which they all felt at his decease, also their satisfaction that he was able to live a long life, and to live it well. He might also say, that in the persons of his son, one a pharmacist, and another a distinguished medical man, the name of Savage was never likely to lose the respect which their late friend had secured for it.

Mr. Atkins said he should like to support this proposition. In common with several of the older members of the Council he claimed the honour of an intimate friendship with the late Mr. Savage; he had stayed at his house on several occasions, and knew his domestic life. A more charming life he had never met with, and he was sure that the expression of regret and sympathy which the Council might send would be received by the lady who survived him, and who was deeply attached to him, with very great pleasure. He was an exceptionally bright and cheery man, and the extreme youthfulness of his manner and mind at his advanced age was quite marvellous. It was remarkable the interest he took in the work of the Society and of the British Association, at whose meetings for many years he was a constant attendant, and if any one wanted a minute reproduction of the transactions of the Society he would find it in the carefully annotated records which Mr. Savage preserved.

The suggestion of the President was unanimously agreed to.

AUGUST COUNCIL MEETING.

It was resolved that the next meeting of Council be held on August 8 instead of August 1.

MEETING OF THE EXECUTIVE OF THE NORTH BRITISH BRANCH.

A meeting of the Executive of the North British Branch was held in the Society’s House, 36, York Place, Edinburgh, on Thursday, June 28, at 12 noon. Mr. J. Laidlaw Ewing was also allotted to the North Branch.

Currie, Glasgow; Davidson, Montrose; Ewing, Gibson, Henry, Lunan, and Noble, Edinburgh; Fisher, Dunfermline; Johnston, Paterson, and Strachan, Aberdeen; Kerr, Dundee; Neat, Portobello; and Sutherland, Dumfries.

Apologies for absence were received from Messrs. Huddie, Dundee; Kinnimont and McAdam, Glasgow; and Storrar, Kirkcaldy.

The minutes of last meeting were read and approved. The Chairman intimated that the first business was the election of a Chairman for the ensuing year.

Mr. Johnston moved that Mr. Ewing be re-elected for another year. He was sure it was their unanimous wish that no better Chairman could be found. During the last two years he had been associated with Mr. Ewing as a member of the Executive, and had found him always able and agreeable in the discharge of his duties. In re-electing him there could be no doubt they were doing the best for their own interest, and for furthering the interests of the Society and the business of the North British Branch.

Mr. Currie said he had much pleasure in seconding the motion. Mr. Ewing’s administration had been a marked success, and the state of the poll at the last
election showed that he still retained the full confidence of the Society. The motion was unanimously agreed to.

Mr. Ewing, in replying, said he was much indebted to them for this renewed expression of confidence, and had to thank Messrs. Johnston and Currie for the kind terms in which they had spoken, though he thought their reference to his shortcomings were too severe. His own feeling was that he should have retired at this time, but he was willing to agree to what he understood was a general wish. He had at their request taken in hand the superintendence of the new building operations, and he would endeavour to see that all improvements were carried through the new building would frequently be re-appointed after the lapse of a year, so that, in point of fact, the boards and the examinations would, in my opinion, be extremely to what they were at the present time. There were very good reasons for making the proposed changes, but these he need not enter upon now.

Mr. Nesbit asked if the outside examiners would examine in more than one subject.

Mr. Johnston said the plan was that there would be a different examiner for each of the two subjects, botany and chemistry.

Mr. Gibson said he saw no necessity for these outside examiners at all. He thought they were not at all fit persons to examine pharmaceutical students. What they wanted was good all-round men with a practical knowledge of pharmacy, and not scientific specialists. He entirely objected to the introduction of outsiders in the manner proposed.

Mr. Paterson said he thought the new scheme was a very serious proposal, and ought to be very fully considered. In medicine it was different, because there they had already compulsory classes. But it was a widely prevalent belief that if a certain teacher happened to be also an examiner it was necessary to attend his class, even when it was an extra class, or they would not pass. He was afraid something of the same kind might happen under the new plan, and their candidates would thus require to spend more time and money on their classes. He thought this proposal was a retrograde step, because the Society had not yet instated any outsiders, except in London, which students could attend, and still they did not think it would not be judicious to alter the present plan. He rather thought their young men would fare better at the hands of the present examiners than at those of the outsiders. Until they had reached a more advanced stage he did not think the change would be a good thing. He did not agree with those who appointed professors as outside examiners, because he thought that last year they were insisting that all-round men were what they wanted.

Mr. Lunan seconded the Chairman's motion. He thought the new plan would be an improvement. He differed from Mr. Paterson and Mr. Gibson, and thought the outside examiners might very probably be easier, and would not exact the same amount of detail knowledge that was sometimes demanded by the present examiners.

The Chairman said this was a matter that had demanded the very serious attention of the Council, and in which it had been felt absolutely necessary to make some new arrangement. It was quite possible that had the Council not voluntarily adopted the new scheme it might have been imposed by a power which was behind the Council.

Mr. Sutherland said he was quite sure the new plan would not impose any hardship on the students, but he believed it would rather be acceptable to them than otherwise. The fact was that they had been asking for something of this kind for a considerable time.

The Chairman's motion was then agreed to unanimously.
The Chairman then explained, in reply to an inquiry, that the Council had found it necessary to make a regulation that notice forms for the first examination should be obtainable only from the Secretary.

The Chairman also reported the result of his inquiry as to the sale of such preparations as Easton's and Fellows' syrups, and directed attention to the passage on this point in the President's speech at the last annual meeting in London. That he recommended, as a guide in dealing with such cases.

Lunnon said he wished to give notice that at the next meeting he would move a resolution recommending the Council to consider the desirability of enlarging the Journal. He had no fault to find with the Journal as a record of transactions, but he thought something might be done by the addition of dispensing memoranda and notes and queries, or otherwise, to make it more popular. In many parts of the country the Journal was looked upon as all they got for their annual subscription, and there was a very general desire to see it made more popular. He gave notice now in order that they might consider the matter, and perhaps get the opinions of their constituents as to what could be done to make the Journal more attractive.

Mr. Currie said this was the first meeting of Executive since the decision of the High Court in the Tolmison appeal case, and he would like to say that it had given much satisfaction among registered chemists in Glasgow. The law in Scotland as affecting open surgeries or drug shops was now perfectly clear, and it was plain that these could not be conducted by unqualified assistants, as had hitherto been the case. The Society's officers would now find it much easier to enforce the provisions of the Pharmacy Act, and it was to be hoped this would be steadily and fully done. Unfortunately, as was well known, the opinion of some of the leading pharmacists in Glasgow did not coincide with that of the High Court, but he was sure the trade generally in Glasgow would give the Society every support in carrying out the law.

The Chairman said he was sure the recent decision was a matter of much satisfaction to them all. Those in Glasgow could say by giving information of offences and preserving a judicious reticence as to the operations of the Society's officers. He trusted the decision would do much in helping those who were endeavouring to improve the status of pharmacy in Glasgow.

Mr. R. H. Parker (Vice-President), in introducing the discussion, drew particular attention to the suggestion already made of the voting papers. The allowed disadvantages of the present system were first considered.

1. That the voting paper system gave the opportunity for canvassing and advertising appeals on behalf of special candidates, thereby placing at a disadvantage the third of the voting papers; consequently those who had any funds at all felt compelled to sacrifice their scant resources for electioneering purposes in order to stand a good chance of success.

2. That the Benevolent Fund Committee, having carefully investigated each case, are much more capable judges of their relative merits than the subscribers would be.

3. That the publicity attached to the system is unkind to the candidates.

The possible objections to the alternative system of electing candidates privately by the investigating committee at the next annual meeting were:

1. The Committee would find it difficult to carry out the highest ethical ideal of true benevolence, their judgment might be warped by personal sympathy, and would be open to the suspicion of favouritism, especially as regards previous membership of the Pharmaceutical Society.

2. The abolition of the voting paper would be like stopping an advertisement.

3. The average subscriber likes to receive a voting paper, and its disappearance may signalise cessation of a great many subscriptions.

Reviewing the whole question, Mr. Parker considered the voting paper system to be preferred (if modified according to the suggestions embodied in the resolution he would propose), because:

1. The Committee need only select as approved candidates those whose merits they considered equal; if any year these should not exceed the number of vacancies, there would be no voting.

2. If the equally meritorious cases exceed the vacancies, then an election by subscribers' votes would be quite free from suspicion of favouritism.

3. Urgent cases unsuccessful one year may be immediately assisted in a substantial manner from the Casual Fund, and are fairly certain of success at the next election by the cumulative feature of the voting paper system, and all cases once approved have an increased chance each year.

Finally, if the candidates' names be not published (the list appearing on the Voting Paper under letters or numbers), and if the Council openly discourage canvassing, the objections on these grounds would not apply; he would therefore submit to the meeting the following resolution:

"That this meeting of the Western Chemists' Association considers that the election of Benevolent Fund annuitants should be conducted as hitherto, but by the issue of voting papers to the subscribers, except as regards the publication of the names of the candidates, these being replaced by letters or numbers; also, that a notice should be given on the voting paper calling attention to the possible unfairness of canvassing cards and advertisements, and urging each subscriber to vote independently upon the official description of the case."

Mr. Marsh seconded the resolution, and said he much approved of the proposition to substitute letters or numbers in place of the candidates' names, as he thought it would spare them much unnecessary pain, as having their names published with details of their cases must be very harrowing to their feelings.

Mr. Hyslop said he must oppose the resolution, as he felt that the election of candidates could be carried out on a much fairer basis by selection by a committee appointed for the purpose.

Mr. Tait, who was in favour of the resolution, more especially as regards the omission of the candidates' names from the voting papers.

The President, having said a few words in favour of the resolution, put the same to the meeting, when it was carried by a majority of ten to one.

The meeting having been adjourned, the next meeting of the Association being announced for the third Wednesday in October.
Scottish Transactions.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

A general meeting of this Association was held on Thursday, June 28, Mr. W. L. Currie presiding, when several matters of importance to pharmacists came under consideration. The recent decision regarding the sale of poisons was the first subject to be brought up. The President said that until now the absolute dispensing of poisons by registered men had not been considered necessary, but the decision in the appeal court showed that it behoved them as registered men to look to their position. It was clear that things could not be allowed to go on as they had been going. What were they to do in Glasgow, where there are so many doctors' shops? It came to this, that new regulations would have to be made so as to keep registered men from being held up to the public as the worst transgressors. Where a qualified assistant was not kept, suppose the principal leaves the shop, poisons should not be dispensed by an unqualified assistant. Mr. Russell considered this to be the general thing all over the Kingdom a poison. But the enforcement of the Pharmacy Act might be a hardship if it could not reach all offenders, and he again suggested the plan of having a list of all drug shops in the city arranged, to show under what conditions each shop was kept, and how many qualified assistants were employed in each. After some desultory talk about doctors' servants dispensing in private surgeries, the sale of Easton's syrup and Fellows' syrup was taken into consideration. A side issue, however, cropped up in connection with Fellows' syrup in relation to the medicine stamp, when it was laid down as the dictum of the Board of Inland Revenue that no proprietary medicine such as the syrup in question, or chlorodyne, or "Iactopeptine," could be sold alone, whether by prescription or not, without having a medicine stamp attached to the bottle or packet.

The President mentioned two alternatives to adopt in the sale—either to enter it in the prescription book with the name of the purchaser, putting a number on the label, or let it be sold as a preparation of a chemical under the first part of the schedule of poisons, to be registered in the poison book with the signature and address of the purchaser.

Mr. D. S. Robertson moved that the plan of entering in the prescription book should be adopted. Mr. McCowan, Paisley, seconded it as the easiest way out of the difficulty.

Mr. Leing moved an amendment that it be labelled poison, and have the dose stated, with the name and address of the seller. Mr. A. McKellar seconded. On being put to the vote, three voted for the amendment and four for the motion, the majority abstaining from voting. The motion, however, was accepted as a suggestion all members were expected to adopt. The draft Pharmacy Act Amendment Bill then came to be considered, when Mr. D. S. Robertson moved that it be approved as it stood, and efforts made to strengthen the hands of the Pharmaceutical Society. Mr. McCowan seconded. An amendment, that there should be no limit nor distinction between pharmaceutical chemists and chemists and druggists in eligibility for election to the Council was moved, but found no second. The motion consequently being negatived, the meeting was closed with applause. The President advised members to wait until the Bill was in Parliament, when suggested alterations could be considered in committee, as the great mistake was preventing bills from reaching the House by blocking them. He then called upon Mr. J. Anderson Russell to bring forward his motion. Mr. Russell said:—

Mr. Chirman and Gentlemen,—My object in asking your careful consideration and opinion of the subject of this motion is to prevent discussion throughout the trade, in the hope and expectation that thereby a good understanding shall be arrived at as to the positions pharmacy and pharmacists should occupy, and that then detailed regulations may be submitted to and endorsed by our Legislature to ensure to them that position.

There is so little time at our disposal to-night that I must not say so much in support of the motion as I might have done otherwise, but I hope to be able on a future occasion, if called upon, to deal with the subject more in detail, and to answer any objections which may be urged either in our own Association or elsewhere.

The fitness of the phrase "Pharmacists for Pharmacy and Pharmacy for the Community" is so evident that no explanation should be required. It is not a rejection of medical practitioners and charlatans, but an expression of the idea that Pharmacy for Pharmacists," is so generally adopted as a guide that I feel compelled to emphasise the difference between the two views. I appeal to you to bear in mind throughout this discussion the absolute necessity of maintaining before you the special purpose for which Pharmacy exists. We should realise that it is nothing short of political and moral insanity to have incompetent persons attempting to carry out that purpose, while specially trained and capable persons are thereby to a great extent prevented from exercising their special functions.

That is wherein the Pharmacy Act of 1868 fails to accomplish what is evidently its aim, for it is a fact that, though it requires proofs of competence from persons "known as chemists and druggists," any person, however ignorant, may quite lawfully enter upon that business, provided that he does not assume the title, and that he stores clear of poisoned poisons.

The only good reasons for employing inadequately trained persons at all in work such as ours are the want of a sufficient number of trained persons to accomplish it, and the necessity of training. Even then they should be under supervision.

Thus far, gentlemen, I think you must be with me, and if the clauses of this motion appear to you calculated to secure that very proper condition, you must approve of them. You have no alternative.

In addition to competence, the great trust confided in pharmacists demands that they shall be conscientious, trustworthy persons.

We cannot create or guarantee moral worth by any amount of legislation, but we may and should suppress flagrant abuse of privileges and immoral doings by punishment of offenders or by taking away those privileges.

In this motion there is submitted a plan for the suppression of doings considered by the pharmaceutical body detrimental to pharmacy and dishonouring to pharmacists, and if the arrangement appears to you calculated to accomplish what I have just indicated, again I say you must approve of it; you have no alternative.

For the application of laws to any body in the community individual registration is necessary in order to identify its members. It would be inaccurate to say that our present system of registration embraces within it all persons engaged in pharmacy; it only includes those whom we call "qualified."
Therefore any laws made to apply to pharmacists would be to order a present system, apply to them whom we call "unqualified," and they would be quite inadequate to regulate pharmacy. The terms "qualified" and "unqualified" are not good for describing the persons intended.

I have selected the terms "graduate" and "undergraduate" as being more distinctive. I have no desire to multiply titles; however, the words are only descriptive. You must understand to be meant the persons whom the words describe, call them by what name you may.

In the event of a register being kept of all persons engaged in pharmacy, each individual could then be made subject to the pharmacists' law, and his position would be as the law decreed.

The registration of open shops would greatly facilitate the full enforcement of the law, which at present is a matter of extreme difficulty and well-nigh impossible. Since all engaged in pharmacy would be interested in and benefited by its laws and regulations, it is but just that all should contribute to the support of its government. My line of reasoning would lead to the conclusion that the community should support it, but if pharmacists do so first, the section of the community benefited will do so directly and fairly and at the same time enjoy the whole privileges obtainable, and should therefore form part of the Pharmaceutical Society, which would then represent all persons engaged in pharmacy.

For the purposes of the fourth clause there is difficulty in precisely defining the province of pharmacy in a single phrase. The phrase "compounding or distributing" is more comprehensive than "compounding or selling," and the phrase "excepting under certain specified circumstances" provides sufficient latitude, when you come to details, for correcting what is defective in the definition.

"Selling" might also be included.

If a more suitable definition can be found, well and good. Remember, this is not the text of a pharmacy bill, but the basis on which to build one.

In restricting the compounding and distributing of medicines, supervision of their acts to registrants and graduates, the only personal effort upon them would be extension of their privileges, and nothing personal could possibly be detracted from them by the suggested altered position of the undergraduates. Undergraduates would be placed in relation to medicine in such a way that they now occupy in relation to scheduled poisons, but they would have privileges beyond the ordinary public, whilst at present they have none.

It is necessary to limit the power of supervision in order that it may be a reality and not a farce.

I am of opinion that an undergraduate should have passed the first examination before being registered, and that he should be aiming at becoming a graduate.

In making these alterations a concession might be necessary, as in former enactments, in order to allow unqualified persons at present engaged in pharmacy to continue doing that which is at present legal for them to do.

The motion contains no reference whatever to the first examination or to a concession. These are matters dealt with in working out details, and I comment upon them now simply to show that certain alternatives are not incompatible with the intention of these clauses.

If it be provided for the sake of pharmacy that it shall be conducted by pharmacists only, it necessarily follows that pharmacists shall have a monopoly of that business. We cannot prevent that. It is a result, however, which I think no pharmacist will object to, and every reasonable person will at once admit the justice of it.

In the fifth clause, the Pharmaceutical Society is named as the proper body to control the conduct of pharmacists. At present I know of no person or body more suitable for that purpose. Of course, every safeguard would have to be provided that justice might be done to alleged offenders.

The increasing and highly beneficial influence resulting from the control exercised by the General Medical Council over the conduct of medical practitioners presents an argument of fact, in favour of granting similar power to the Pharmaceutical Society, more than equal to any theory I could submit.

In pharmacy under these regulations it would be even more effective.

That there is room for its exercise must be patent to all observers.

Here, again, note the necessity of all persons engaged in pharmacy being registered, for without that, disciplinary measures would lose their force and value.

The provision of the sixth clause is necessary in order to enable the regulations to be enforced.

Having endeavoured to make the motion as clear as possible, and having, I trust, convinced you of its desirability, I now move—

That the members of the Glasgow and West of Scotland Pharmaceutical Association, taking as a watchword, not "Pharmacy for Pharmacists," but "Pharmacists for Pharmacy, and Pharmacy for the Community" (these being the relative positions each should occupy), consider it most desirable that the changes mentioned in the first clause of the resolution should in all cases extend to graduates, and "undergraduates" registration to be equal to membership, association, or apprenticeship of the Pharmaceutical Society.

That all open shops for the sale of drugs be registered.

That registration be maintained under an annual licensing fee.

That medicines be compounded or distributed by registered graduates only, or by registered undergraduates under the supervision of a registered graduate, excepting under certain specified circumstances; a limit to be placed on individual power of supervision.

That the Pharmaceutical Society be empowered to exercise control over the conduct of its licencess, even to removal of names from the registers if need be.

That breach of the second or fourth of these clauses shall constitute a penal offence.

Mr. D. S. Robertson seconded the resolution, not altogether in detail, but as considering that the principle was good. Mr. Laing congratulated Mr. Russell on the fruits of his mind, and said if the question of limited liability companies was to be dealt with, this motion indicated the only practical way. If pharmacy was to be kept from that sphere of degrading money-grubbing competition, which was the curse of the age, the motion offered the only way. The President, while congratulating Mr. Russell on his effort, desired to emphasise the fact that the motion had not been adopted altogether by the Association, but, owing to the lateness of the hour, its further consideration necessitated an adjournment of the discussion. The election of a district secretary for the north-east was left in the hands of the council, and the meeting closed.
ABERDEEN AND NORTH OF SCOTLAND
SOCIETY OF CHEMISTS AND DRUGGISTS.

The annual excursion of this Society took place in
beautiful weather on Tuesday, June 26, to Balmoral and Loch Muick, about thirty members and friends
leaving Aberdeen by the Deeside train for Ballater at
8 a.m. Arrived at Ballater the company proceeded to
the Lassachan Arms, where they were met by Her Majesty’s Commissioner, Dr. Poflett, who, having obtained special permission from
Her Majesty, conducted the party over the grounds,
through the castle, the garden, the stables, and the
dairy. Before leaving Balmoral the President of the Society,
Mr. Johnston, expressed the most grateful
thanks of the party to Her Majesty, and their con-
gratulations on the birth of another heir to the crown.
The return drive was by the new road over the hills to
Altanguslaich, from which there is a magnificent view
of the castle and grounds of Balmoral, with the snow-
clad summits of CairnToul, Cairngorm, Ben Ann, and
Ben Macdhu filling up the background. Pausing
almost under the shadow of Lochnagar, the
party then proceeded by the Queen’s private
drive to Glenmuick, and arrived at Ballater about
4 p.m., where dinner was served in MacGregor’s
Lavendar Arms Hotel, with Mr. Johnston in the chair.
After dinner and the loyal toasts, Mr. J. Paterson pro-
posed “The Pharmaceutical Society of Great Britain,”
and the chairman replied; Mr. Craig proposed “The
North British Branch,” and Mr. J. Laidlaw Ewing,
Chairman of the Executive, replied; Mr. Rutherford
Hill proposed “The Aberdeen and North of Scotland
Society of Chemists and Druggists,” and the Vice-
President, Mr. Mortimer, replied. Other toasts
followed, and after dinner some of the party climbed
the steep ascent to the summit of Craig Chollach, and
were rewarded by a splendid view of the encircling
mountains and the valley of the Dee. The company
left for Aberdeen at 7.15, and arrived a little after
9 p.m.

The arrangements were carried out in a very
perfect and successful way by Mr. J. Cruickshank and
his committee.

EDINBURGH CHEMISTS, ASSISTANTS’, AND
APPRENTICES’ ASSOCIATION.

The third botanical excursion of the season took
place on Wednesday, June 20, to Colliston Dell, start-
ing by train from Princes Street Station at 8.30 p.m.
The weather was fine, and there were about fifty
members present, Messrs. W. Duncan and D. McEwan
acting as conductors. A large number of specimens
were collected, among them being: Euphorbia amygdaloides,
Cyclamen hederifolium, Helenium autumnale, Sambucus nigra,
Symphytum officinale, Valeriana officinalis and V.
praecox. Specimens of the three Geum, G. rivale,
G. intermedium, and G. urbanum were also found on
the spot from which Dr. J. M. Macfarlane obtained
the plants used in his research on the morphological
relationships between the genus and hybrids, which
were communicated to the Royal Society of Edinburgh a
few years ago.

Parliamentary and Law Proceedings.

POISONING CASES AND INQUESTS.

HOSPITAL DISPENSING OF POISONOUS LOTION.

On Saturday last Dr. Wynne Westcott held an
inquest at Green concerning the death of
Harry Francis, 35, a chair maker, 52, Gossett Street.
He had not been in good health lately, and had been
receiving medicine and a lotion from the City
and East London Dispensary, Finsbury. On Monday last,
on returning home about dinner-time, he went up into
his room. A few minutes later his sister saw him
leaning against the mantelpiece. She said, “What is the matter?” He replied, “I have taken a dose of
the lotion in mistake for my medicine.” A doctor who
was sent for said on arriving that Francis was dead.
It was stated that Francis was eccentric, but had never
before been known to have been improperly dispensed
with.
The lotion bottle, which was produced in court, had
no label, and the coroner remarked that if a chemist
had supplied it he would have been liable to prosecu-
tion. Dr. Ernest Walters attributed death to poison-
ing by carbolic lotion. The jury, after passing severe
comments on the bottle being sent from the information
without any label, returned the following verdict,
“That the deceased died from poison taken by mis-
adventure.” They requested the coroner to write to the
dispensary to the effect that all bottles containing
poison should be properly labelled.—Morning.

ACCIDENTAL POISONING BY CARBOLIC ACID.

On July 3, an inquest was held at Leeds on the body of James Williams (49), who took a draught from a
bottle containing carbolic acid, under the impression
that it was port wine. Verdict: “Death from misad-
venture.”—Yorkshire Post.

On the same day, an inquest was held at Mansfield,
concerning the death of Matthew Hudson (9), who had
drank some carbolic acid sheep dip from a bottle
found on the road side, which he supposed to contain
porter. Verdict: “Death from misadventure,” and
the jury suggested that the bottle should have been
labelled poison.—Nottingham Guardian.

PROCEEDINGS UNDER THE SALE OF
FOOD AND DRUGS ACT.

ADULTERATED PEPPERMINT LOZENGES.

On Wednesday, June 27, at the North Holland
(Boston) Petty Sessions, before Dr. Mercer Adam, the
Rev. S. Staffurth, the Rev. J. B. Sparrow, Mr. C. T.
Tunnard, Mr. S. Waddington, and Mr. R. Gleds,
William Sharp, grocer, Donnington, was charged with
having sold perpermint lozenges adulterated with raw
potato starch. There were two summonses, the first
charging the defendant with having adulterated the
lozenges as an article of food, and the second
charging him with having adulterated the lozenges
as a drug, so as to injureously affect its
quality and potency. Mr. H. Smith defended.
Superintendent Crawford proved the purchase of
the lozenges, and Mr. C. H. Southwell, the county
analyst, said that the lozenges contained not less than
10 per cent. of raw potato starch. The lozenges of the
British Pharmacopœia consisted of sugar, gum acacia
and the medicinal substance they represented. The
use of starch would increase the bulk, weight, and the
profit, and would take the place of much of the gum
acacia. Gum acacia was worth from 1s. 6d. to 5s. a
pound, and potato starch was worth less than 14d. per
pound. Raw starch was considered injurious, as tend-
ing to induce or to aggravate dyspepsia. Dr. Fletcher
also gave evidence in support of the charge, and said
that raw potato starch was injurious to health, and
would have a depreciating effect on any drug with
which it was combined. On behalf of the defendant,
Mr. Smith said he retailed the lozenges as they were
supplied to him, and he was ignorant as to what they
contained. Defendant said he had never had any com-
plaint before. The magistrates dismissed the case, on
the ground that the defendant had acted in ignorance,
but cautioned him against selling similar lozenges in
the future.—Lincolnshire Chronicle.
Reviews and Notices of Books.

The first edition of this work appeared in 1882. The preface states that it is intended for the use of the practitioner, the teacher, and the student, and it may be added that many of the sections are of interest to the philosopher, whether he be of the medical profession or not; for, comparison of the first with the second edition leads to full appreciation of the great advance that has been made in the course of the last twelve years in the highly complex science of medicine—the mother-science out of which have sprung the roots of many of the most important sciences, such as chemistry and biology.

Scanning the list of contributors to the dictionary it is at once seen that the work is authoritative in the highest degree. In every language there are one or more encyclopedic works which are the just object of national pride. Such are in general literature the lexicon of Samuel Johnson for England, and the great dictionary of Littré for France, and in medicine the great German cyclopedia, edited by von Ziemssen, and in England the present work, which does honour not only to Sir Richard Quain and his assistant-editors, but to the medical profession of England, and should be a source of pride to the English-speaking race.

The value of the work to thinkers outside the pale of medicine has already been mentioned, and allusion may be made to some chapters which catch the eye in even cursory perusal and give profit in the reading. The article on personal health by Dr. Reginald Southey, like many of the sections, appears in the same form in both editions, a striking testimony to the soundness of the original work. It is difficult to refrain from making here a few quotations: "Let us pass from the exercise of the muscles to that of the brain; since here, too, the hygienist may be expected to give a few words of advice as to what is proper and profitable in mental work, and what is improper and likely to prove detrimental to the cerebral organs. Our own experience confirms that of others, that most brains suffer more from rest than overwork.

"Exercise is as essential for the healthy nutrition of the cerebral as it is for that of the muscular tissue; and without regular employment up to the fatigue-point no high quality of intellectual condition is ever attained. Fret, hurry, worry, and the endeavour to accomplish some task in too short a time is what wearies and wears the thinking organ." This brief extract will serve to show that a part at least of this article is to be understood by the laity. Another indicates periods of natural illness, and is of interest to those healthy persons who, in a busy life, think of their physical state only when they feel unable to cope with tasks ordinarily easy to them: "Dr.

Waterhouse notices the three following periods as very important in every human life, as sickly or mortifying times. The first he has noticed to befal males chiefly at thirty-six years of age, when the lean person becomes fatter, and the fat leaner. The second sickly period happens at some time between forty-three and fifty, and lasts a year, or perhaps two. During it the complexion fades, the appetite fails, the tongue becomes furred at the slightest over-exertion of body or mind, the muscles are flabby, the joints are weak, sleep is unrefreshing and the spirits droop. It is no particular organ that suffers, but a uniform deterioration that is experienced . . . . . This observation of Dr. Waterhouse has, according to the experience of many, much justice in it; as also that between sixty-one and sixty-two a similar deterioration of health takes place, but with aggravated symptoms." These periods or cycles of natural illness, together with those that are more generally known, puberty and the climacteric, no doubt constitute the opportunity of the unscrupulous and of the charlatan. The terror which arises from a natural time of unfitness is in many minds not to be dissipated by the sober reassurances of honourable medical men, and drives the sufferer to read the puffs which disgrace almost every journal in this country. The net is so carefully spread that it is capable of catching every kind of game, and the lure is furnished in the shape of testimonials, many of them written by medical men who appear incapable of resisting the temptation of seizing the only opportunity they can have of seeing their names in print.

Turning to the new articles, which give an index of the direction of medical progress in the last twelve years, they are found to be based chiefly on biological discoveries. Thus the original article which appeared under the head of "Micrococci," by Professor Greenfield, in the first edition, is replaced by a much longer article on "Micro-organisms" by the same author and Dr. Robert Muir. This section is of the highest interest even to unprofessional readers, and when it is considered that it is but the condensation of an immense amount of scientific work it is then realised that the last twelve years of medical endeavour are perhaps fuller of fruit than any equal period of time in the whole history of medicine. Reflection here affords a ready answer to the well-meaning but illogical persons who strive by the distortion of facts to influence popular opinion, with the object of the suppression of experimental pathology, and who, though they do not hesitate to use horses that have suffered exculculating pain and unsewing mutilation in order to make them useful, fly into hysterical excitement at the idea of experiments which inflict not so great a pang as the lash their coachees are allowed to ply freely when their masters are in haste to catch a train.

In a world of pain and struggle people may be thankful that so much human and animal life and suffering has been saved by the practical application at the hands of great men, such as Lister and MacEwen, of the bacteriological knowledge of which Pasteur and Koch laid the foundations.
The last portion of this section succinctly relates the new discoveries initiated by Laveran with regard to the malarial fevers. It appears that these diseases which decimate our men and beasts in many of our Indian and other expeditions, and shut off from colonial enterprise many thousands of miles of the earth’s surface, are caused by microscopic animal parasites. Other important biological chapters are those on phagocytosis and immunity, by Dr. Sidney Martin, and those on entosos and paracopemias, by Mr. Bland Sutton. Phagocytosis is defined as “the property possessed by certain animal cells of taking into their substance solid particles, which may be either rejected, or used by the cell for its nutrition, or, when the solid mass is living, may destroy the cell.”

Dr. Martin’s brief account of the work of Motschikoff gives an epitome of one of the most striking of the true romances of science.

Bacteriology has, as well as its biological, a chemical aspect, which is well treated by Dr. A. P. Luff under the head of pimelains.

Thus it may be seen even by one not well versed in medical matters that the work is in the highest and best sense of the word authoritative, that it contains a sufficient account of what is firmly established of all the discoveries of the last twelve years bearing directly on medical practice, and perhaps those who follow all medical matters closely may notice that some questions still under controversy have not been alluded to. This reference is perhaps wise in a work of reference of this kind. In conclusion, the opinion can but be repeated that the two volumes constitute a legitimate source of pride and satisfaction to those responsible for its production, and it may be added that the work cannot fail to influence in the right direction medical thought and education.

Notes and Queries.

DISTINCTION BETWEEN ANTIPYRINE AND TOLPYRINE.

Tolpyrine is a homologue of antipyrine, obtained by a similar process, which differs in the substitution of paralolinide for aniline as the starting point, the intermediate product being paratolylhydrasin instead of phenylhydrasin, as in the case of antipyrine. As a means of distinguishing the two, according to Stock, weak solutions of tolpyrine are affected and even precipitated by a 15 per cent. soda solution, though even concentrated solutions of antipyrine remain unaltered. The melting point of a mixture of the two compounds is also said to be lower than that of the one which melts at the least elevated temperature (Pharm. Zeit., and Répertoire).

DETECTION OF MIXED OILS.

It is proposed by de la Royère to detect vegetable or animal oils in mineral oils by means of a solution of fuchsin decolourised by a caustic alkali. The solution employed should contain 50 Cgm. of fuchsin per litre of water, and caustic soda solution be added until decolourisation is just effected. On adding to a few drops of the suspected oil in a capsule, two drops of this reagent, the mixture is said to remain colourless if the mineral oil be pure, but acquires a rose tint if vegetable or animal oil be present. The method is said to operate successfully with colza, hemp-seed, linseed, olive, marigold, cotton, palm, castor, almond, sesame, neatsofoot, and cod liver oils (Res. inter. de falc., through Répertoire).

TURPENTINE IN BALSAM OF PERU.

According to the Bollettino chimico farmaceutico pure balsam of Peru is coloured cherry red when treated with pure sulphuric acid. If turpentine be present, however, the mixture darkens and sulphurous solid is liberated (Répertoire).

ANTIKAMNIA, PYRETINE, AND PHENATOL.

These are American preparations, and consist of mixtures of substances possessing antipyretic, analgesic, and antineuralgic properties. Antikamnia is said to be a mixture of sodium bicarbonate, acetenilide, and caffeine. Pyretine, as analysed by A. L. Weller, is composed of acetenilide, 58.7 per cent.; caffeine, 6.8; calcium carbonate, 13.4; and sodium bicarbonate, 19.5. Phenatol he describes as a mixture of acetenilide; sodium bicarbonate, carbonate, sulphate, and chloride; and caffeine (Pharm. Zeit., and Journ. de Pharm.).

THYROID PILLS.

Thyroid glands are made into pills by Benson, of Copenhagen, by the following method:—The glands are freed from grease and enveloping membranes, then finely divided, spread in thin layers on plates, and dried in a stove, at a temperature between 40° and 50°. When destocination is complete the matter is powdered, then washed with ether to remove any remaining traces of fat. Finally, the powder is massed with simple syrup, and the pills when cut are rolled in cocoa to mask the odour of the glands (Pharm. Zeit., and Journ. de Pharm.).

SOLUTION OF FERRI PYROPHOS.

"Nemo" asks "why a solution of ferri pyrophos in water (strength 1 in 5), to which is added 10 per cent. of S.Y.R. (60 c.p.), should go as thick and viscid as treacle if kept for some length of time?"

Ferrum Pyrophoricium, of the British Homoeopathic Pharmaconia, is a scale preparation, containing about 55 per cent. of pyrophosphate of iron, Fe₃P₂O₇, combined with citrate of soda. Another form of this preparation contains ammonia in place of soda. Either form is readily soluble in water, but is precipitated by adding excess of spirit, and in the instance given the saturation point is probably exceeded. Possibly, too, the peculiar appearance noted may be due to other phosphates of iron, present as impurities. Perhaps some readers of the Journal may be able to offer further explanations.

PURE ETHYL NITRITE.

"Assistant" inquires "whether pure ethyl nitrite is such an unstable compound as stated, and only procurable in solution?"

Pure ethyl nitrite cannot be kept under ordinary conditions without decomposition taking place. The most stable preparation is probably a 2 per cent. solution in absolute alcohol, to which 5 per cent. of
Correspondence.

Tests for Gallic and Tannic Acids.

Sir,—The so-called tests for gallic and tannic acids given in Mr. Davis' letter in last week's Journal are strictly on a par with the information contained in his recently published handbook of 'Practical Histological Botany,' which was so fitly reviewed in the Pharmaceutical Journal of June 2. It is a fact well known to the most elementary student of chemistry, that distinguishing tests for acid solutions, when applied to the same, give different results. Acid solutions will neutralise alkali, and for gallic acid with what is practically alkaline barium hydroxide in the first instance. Hence his discovery of a new test is utterly worthless and inaccurate. If the test be applied to the two acids under identical conditions the result is the same in both cases, namely, a white precipitate, which rapidly turns dirty blue. Secondly, the behaviour of these two acids towards solutions of neutral and alkaline salts of barium and other metals is already well known by most workers who have had any practical experience of testing the various tannins. I have often used barium chloride solution as a test for a tannin and would refer Mr. Davis to the useful tables in Allen's Commercial Organic Analyst "How To Do It." 

A. H. Mccoll.
Practical Pharmacognosy.

(Continued from Vol. xxiv., p. 959).

SYSTEMS OF TISSUE.

BARKS.

In order to take an intelligent and comprehensive view of the structure of medicinal barks, it is desirable that the manner in which the primary and secondary tegumentary tissues develop should be clearly understood by the student, and the following summary of the latest information on the subject, as presented by Strasburger, Vines, and other eminent botanists, may therefore be found of value as an introduction to practical work.

Differentiation of Growing Points.

The growing points of stems and roots consist of small-celled "meristem" or generating tissue, in which the cells still continue to divide and subdivide to form permanent tissue. The cells are all embryonic, yet they are so far differentiated that three well-defined rudimentary tissue systems can be distinguished. Thus, the growing point is found to consist (1) of a superficial layer which is continuous with the epidermis and is, in fact, the embryonic epidermis or "dermatogen"; (2) one or more layers within the dermatogen, constituting the "periblem," continuous with the fundamental tissue outside the bundles (extra-vascular); and (3) the "plerome," a solid mass of somewhat elongated cells in the middle, which gives rise to the axial cylinder of tissue (the "stelo") in the plant.

Nature of the Epidermis.

The "epidermis," or primary tegumentary tissue, may be described generally as the external layer of cells covering the body of the young plant, and, in the most exact meaning of the term, can only exist where there is a definite "dermatogen," i.e., in the Phanerogams and the roots of the Pteridophyta. Usually, however, the application of the term is confined for convenience to the primary tegumentary tissue of the shoot, that of the root, apart from the root-cap, being referred to as "epiblema."

The epidermis consists, in the great majority of cases, of a single layer of cells, but in some foliage leaves two or more layers are found. The continuity of this enveloping membrane is interrupted in certain cases by well-defined apertures, termed stomata, which permit communication between the intercellular spaces of the internal tissues and the external air. The epidermal cells themselves are characterised by the thickening and cuticularisation of their walls, the external wall being usually much more thickened than the others. The outermost layer of the epidermis—known as the "cuticle"—is also clearly defined from the inner layers, which are cuticularised to a less extent.

Cortex or Hypoderm.

Immediately within the epidermis occurs the cortex, or "hypoderm," which appears to be developed from the "periblem" as the epidermis is developed from the "dermatogen," and may consist primarily of one or more layers of collenchymatous or sclerenchymatous supporting tissue. In roots, the hypoderm is distinguished as the "exodermis."

Fig. 21.—Bark of Rhamnus purshiana. Transverse section—K, cork; P, parenchyma; Pp, primary bast; Bf, bast fibres; Bp, bast parenchyma; M, medullary rays. x abt. 120. (Moeller.)

The effect on the epidermis and cortex of the development of secondary tissue in the interior of a young stem or root is one of pressure and tension; the radial growth of the tissue of the central cylinder (stele) exerting a radial pressure upon the external tissues, while the tangential growth of the stelar tissue exerts a tangential tension on them. The radial pressure tends to cause more or less rapid
obliteration of the softer cortical tissue; whilst the tangential tension stretches the cortical cells and tends to cause them to grow tangentially, and multiply by radial division. According as the radial pressure or the tangential tension predominates, the primary cortex is either rapidly destroyed, or persists for a very considerable period.

**Secondary Outer Tissues.**

The secondary outer tissue of the stem is formed by the "phellogen," or cork-cambium, a layer of special merismatic cells formed from the epidermis, or, more commonly, from the outermost or other

---

Fig. 22.—Transverse Section of Young Canella Bark. *Ep,* epidermis; *C,* cork; *CC,* cork cambium; *Phell,* phellogen; *O,* oil cell; *Coll,* collenchyma; *PB,* primary bark; *Scl,* sclerenchymatous fibres; *p,* primary bast; *pm,* primary medullary ray; *sm,* secondary medullary ray; *C,* cambium. x100. (Greenish).

layer of the cortical parenchyma. Sometimes, even, it may be formed from the "endodermis," or bundle-sheath, or, again, from a layer of cells belonging to the "pericycle" or peripheral tissue of the central cylinder of the stem. By repeated centripetal division the "periderm," constituting the secondary tegumentary tissue of the stem or root, is formed on the outer side of the phellogen, and by repeated centrifugal division the "phelloderm" is formed on the inside. The primary phellogen has frequently but a limited period of merismatic activity, though in the stems of the beech, cork-oak, silver fir, etc., it is persistent. When it has been converted into some form of permanent tissue a new secondary phellogen is developed internally to the first. This also is of limited duration, and the process is repeated at intervals, until at last the phellogen layers penetrate into the bast-tissue of the bundles.

Since the walls of the cells constituting the periderm generally become completely suberised, the tissue is often termed "cork." It contains no intercellular spaces, and consists of more or less cubical parenchymatous cells, which are sometimes elongated tangentially; they gradually lose their protoplasmic contents and become filled with air. In the periderm of both stems and roots there are frequently found "lenticels," which correspond to the stomata of the epidermis, and, like them, serve to admit air to the internal tissues. In branches of one year's growth the lenticels are seen as brownish or whitish specks.

On account of the properties of its cell walls the cork offers an obstacle to the passage of water. Consequently, all the tissues external to it dry up, and are eventually exfoliated, and the more deeply the phellogen is situated, the greater is the amount of primary tissue thus thrown off. "In a few trees, as the silver fir, the primary periderm persists for some years, or, as in the beech, during the whole life of the tree; the outer cork-cells split off as the trunk of the tree increases in thickness, while the phellogen, growing and extending in a tangential direction, gives rise to new layers of cork. When, as in most cases, new layers of phellogen arise after a few years in the deeper tissues, leading to the development of corresponding layers of periderm, an external investment of a more or less complicated structure comes to be formed. In consequence of the impermeability to water of these secondary layers of periderm, all the tissues lying externally to them become dried up. These dried-up tissues, which may belong to different tissue-systems and include the most various forms of cells, constitute what is known as "bark."" (Vines)

**Constitution of Bark.**

It will be apparent, therefore, that barks, on account of their frequently extremely complicated structure, may require very careful study if their elements are to be properly differentiated and recognised by the student. Those used in medicine are almost exclusively obtained from the stems of dioxytelsons or gymnosperms, but few being obtained from the roots; whilst monocytelsons have no true bark, because they do not increase in thickness by secondary growth such as occurs in dioxytelsons.

Technically, the bark is regarded as including the whole outer layer of stems and roots, separated from the wood by the cambium layer. Very young barks only are covered by the epidermis. Where the latter is replaced by cork, the outer layer or periderm is distinguished as the "exophloium," or outer bark; the middle bark, consisting mainly of the primary cortex, composed of parenchyma containing chlorophyll, is the "mesophloium"; and the inner bark or liber (bast) is the "endophloium." This inner or secondary bark is composed of axially elongated bast parenchyma, bast fibres, and sieve tubes, i.e., the phloem portion of the fibre-vascular bundles, and is intersected by medullary rays, formed of radially elongated parenchyma.
The outer bark has been assumed to contain no active constituents, and is usually rejected, though, if thin, it is often allowed to remain attached, and affords a useful means of distinction. In the parenchyma of the middle bark may be found cells containing volatile oil, resin, mucilage, or crystals (oxalate), and stone cells (sclerenchyma) and collenchyma are not uncommon. Secondary cork may be formed in the interior of the bark tissue, and then tends to become thrown off in scales which include the portions of tissue external to the bands of cork. This peculiar form of suberous tissue has been distinguished by the term "rhytidoma" (German "bohrte"), and where it has formed and been removed with the external tissues, the inner bark alone remains, as in the case of elm and coto barks. Long, soft, intertwining bast fibres also assume an intense red colour after prolonged treatment with aqueous extract of cochineal with acetic acid or alum. Other elements absorbing this stain are decolorised by after-treatment with hydrochloric or sulphuric acid; but the colouring of the best fibres is thus said to be rendered more intense. If lignified the best fibres assume an intense rose-red colour when the section containing them is treated with hydrochloric acid and then placed in a drop of phloroglucin solution on a glass slide. The plasma of sieve tubes may be coloured by eosine, and the callus by aniline blue or rosolic acid. The suberin of cork cells is insoluble in concentrated sulphuric acid or in cuprammonium, may be extracted from corky tissue by boiling in potash solution, and treatment of thin sections with nitric acid and potassium chlorate results in the partial solution of the cell walls, and separation of yellow masses of ceric acid. Chromic acid dissolves both celluose and lignified cell walls entirely, and renders those containing suberin transparent, dissolving them only after prolonged action. As in the case of lignin, chloro-iodide of zinc colours cork cells yellow, and Grenacher's alum carmine does not affect them, whereas pure celluose is coloured violet by the first and red by the second.

*Rhamnus Bark.*

The barks of *Rhamnus frangula* and *R. purshianus* will be found the most suitable for students to study in the first instance, as the structural elements are more clearly differentiated in these than in many others. A transverse section of *R. frangula* is represented in Fig. 20, where a considerable formation of corky periderm (K) is indicated as constituting the outer bark. The middle bark consists of parenchymatous cells, some of which contain crystals, and at one point (pb) primary bast cells are seen. In the inner bark the medullary rays (m) are distinctly visible, splitting up the phloem, consisting of bast fibres (bf), sieve tubes and bast parenchyma containing crystal cells. A radial longitudinal section is represented in Fig. 23. The bark of *R. purshianus* (Fig. 21) is very similar in its general arrangement, but the development of the sclerenchyma or stone cells (at) is very marked.

*Canella Bark.*

In the case of canella, the relation of the different tissues in the bark is very clearly shown in young bark (Fig. 22). The periderm of old barks often contains groups of sclerenchymatous cells derived from the phellogen. The latter does not invariably include sclerenchyma, however, as that tissue may be partially or entirely replaced by thin-walled, non-lignified cells containing small starch grains or rosette crystals of calcium oxalate; the medullary rays are more or less filled with endodermal cells containing calcium oxalate and numerous oil cells, but the inner bark is present in the largest proportion in mature specimens, and consists of alternate rows of bast parenchyma and sieve tubes. The last-named frequently yield lignin reactions, are bluntly pointed, and have numerous, closely crowded sieve plates on their radial walls. The structural details of canella bark will be found fully described in Professor Greenish's paper at page 793 of the last volume of the Journal.

(To be continued.)
SOME COMMON SOURCES OF ERROR IN TESTING FOR SUGAR IN THE URINE.*

BY SIR GEORGE JOHNSON, M.D. LOND., F.R.S.
Emeritus Professor of Clinical Medicine, and Consulting Physician to King's College Hospital; Physician Extraordinary to Her Majesty the Queen.

It has happened to me during the last quarter of a century or so to be consulted by a considerable number of patients who were being treated for glycosuria, but in whose urine I could find no trace of sugar. As these patients had been strictly dieted, and were taking highly nutritious food, to the exclusion, as far as possible, of saccharine and farinaceous materials, it might plausibly be supposed that the absence of sugar when the patients came under my notice was the result of the treatment. In order to test this they were directed to return to an ordinary mixed diet including sugar, sweet fruits, and starchy food of all kinds. After a week or more of this diet the continued absence of sugar led to the conclusion that a mistake in the mode of testing for sugar had led to an erroneous diagnosis. In nearly, if not quite, all the cases to which I am referring they had the same general characters. The specific gravity was high, 1.030 or more; there was an excess of urea, as shown by the large mass of crystals which resulted from the addition of an equal volume of strong nitric acid to the urine, the mixture being stirred with a glass rod and afterwards cooled, while an analysis indicated as much as 3 per cent. of urea. In none of the cases had there been excess of urine, thirst, or other symptoms of diabetes. The cases, in fact, come under the designation of azoturia. The power of digesting and assimilating nitrogenous food is impaired, there is an excessive excretion of urea, and, as I shall presently show, of other nitrogenous products by the kidneys. Obviously they are not cases in which a highly nutritious diet is likely to be beneficial, but rather the reverse; so that, as often happens, a wrong diagnosis suggested an erroneous method of treatment. Now in all these cases, with one exception, the copper test had been used, either Trommer's process or Fehling's solution. In the one case a highly albuminous urine had been boiled with liquor potassae (Moore's test), and the dark colour resulting from the combination of the sulphur of the albumin with lead in an impure specimen of liquor potassae was mistaken for the brown colour produced by boiling potash with glucose. The explanation of the mistake which have been made in using the copper test for sugar is to be found in the fact that all normal urines contain two substances which resemble glucose in their power of reducing the oxide of copper: these substances are uric acid and kreatinine.

Dr. Pavy† has shown that uric acid accounts for one-fourth of the reducing action of normal urine upon copper solution, and he suggests that the remainder of the reduction is due "to the small amount of sugar naturally present in the urine." "It is doubtful," he says, "if there is any

---

* Reprinted from the Lancet.
† 'Med. Chir. Trans.', vol. lxiii.
reducing properties. It was his discovery that the kreatinine in normal urine is sufficient to account for the total reduction of picric acid when that agent is used as a test, and for three-fourths of the reduction of cupric oxide, the remaining fourth being due to uric acid, that led to the conclusion that no sugar is present in normal urine. Additional evidence of the absence of sugar from normal urine is afforded by the fact that the very sensitive phenyl-hydrazine test gives no indication of sugar in that secretion. It has been suggested that my son’s researches would have attracted more attention if he had given a new name to the substance which he has isolated and analysed, but as it is isomeric with other kreatinines it is, perhaps, sufficient to distinguish it by the name of the “natural kreatinine of urine.”

One advantage amongst others which the picric acid has over the copper test is that it is not affected by uric acid. The result is that the degree of reduction in normal urine is an exact indication of the amount of kreatinine present, and here we have a simple means of testing the accuracy of the results of my son’s researches. This is done by comparing the colour resulting from the application of the test to the urine with that which results from testing an aqueous solution of kreatinine of the same strength as that indicated to be present in the urine; but it must be borne in mind that the reducing power of kreatinine is inferior to that of glucose in the proportion of 10 to 12, so that if the urine tested with picric acid gives a colour which, if glucose were the reducing agent, would indicate one grain per ounce, the kreatinine solution, to give the same colour, would have to contain 1.2 grain per fluid ounce. If the reduction by the urine were 0-8, then as 10 : 12 : : 0.8 : 0.96. The amount of kreatinine would be 0.96 grain per ounce, and experiment confirms the result of the calculation. One point, however, has to be noticed. When the colours resulting from testing urine and an aqueous solution of kreatinine of the same strength are compared, the former is usually seen to be slightly darker. The difference, which is so small as to be incalculable in amount, is due to the colouring matter in the urine, which may be removed by filtering through animal charcoal before applying the test. A very simple experiment shows how minute a quantity of urinary kreatinine suffices to give the characteristic red colour with the picric acid test. A draught of a saturated solution of picric acid is mixed with an equal quantity of water and half a draught of liquor potassae (P.B.). The precipitated picrate of potash is dissolved by raising the mixture to the boiling point. The result is a liquid of a slightly darker yellow colour than the cold and undiluted picric acid solution, but without the slightest tinge of red.† If now

*a single drop of a solution of kreatinine, in the proportion of one grain to the fluid ounce, be allowed to trickle down the side of the sloped tube into the liquid, a bright red colour is rapidly diffused from the top to the bottom of the column of liquid. It may be that the makers of this paper would find it difficult to obtain the genuine urinary kreatinine, which at present is not to be bought from any manufacturing chemist, but they will find that precisely the same result follows the addition of a drop of normal urine to the hot solution of picrate of potash. The proportion of kreatinine in an average specimen of normal urine and in a grain to the ounce solution of kreatinine is approximately the same, and the amount of the agent in one minims of the aqueous solution, as in one minims of normal urine, would obviously be no more than ¼ of a grain.

In using the picric acid test for glucose with a knowledge, which every practitioner should possess, of the reducing action of kreatinine upon that agent, it is scarcely possible to fall into the error referred to at the commencement of this paper—namely, that of supposing that sugar exists in urine which is quite free from that substance. When to a draught of normal urine in a test-tube about half an inch in diameter is added an equal volume of a saturated solution of picric acid and half a draught of liquor potassae, the mixture immediately becomes red, owing to the partial reduction of the picric acid by kreatinine. Kreatinine differs from glucose in the fact that in the presence of potash it exerts some reducing action on picric acid at the ordinary temperature of the air. When kept at the boiling point for a minute the colour is deepened, and in normal urine it may be such as to indicate what, if glucose were the reducing agent, would equal from 0-6 to 1-2 grain per fluid ounce, as shown by the picro-saccharimeter. I have repeatedly shown that a solution of glucose, in the proportion of 2 grains to the fluid ounce of water, when tested as above described, gives so dark a colour that no red light is visible through the middle of the column of liquid. If, therefore, a sample of urine having been thus tested, a bright red colour is transmitted through the full diameter of the test-tube when held up to the light, the reduction is due to kreatinine alone, and no glucose is present. If, however, the colour is so dark as to indicate an amount of reduction equivalent to two or more grains of glucose, this is more than the largest proportion of kreatinine hitherto found in any specimen of urine would account for, and the presence of sugar is indicated. The amount of sugar can be determined after separating the kreatinine by the mercuric chloride process before described.† In liquid also being turbid. A simple test of the purity of picric acid as a test agent is to boil the solution with half its volume of liquor potassae. The result should be a clear yellow liquid, neither turbid nor red.

† In two tables, at pages 550-3 of my son’s Royal Society paper, the highest amount of reduction of picric acid in a large number of samples of normal urine is shown to be 1-2, and the lowest 0-6. In urine of high specific gravity the amount of kreatinine and the consequent reduction of picric acid are found to be increased, together with that of the other normal solids of the urine.
illustration of this the result of an analysis of a urine of high specific gravity may be briefly stated. The specific gravity was 1.035, colour normal; 20 minims added to 2 drachms of boiling Fehling's solution gave a copious precipitate of suboxide of copper. The picric acid process indicated a reduction of 1/8 grain per ounce. After the separation of the creatinine by mercuric chloride the reduction was reduced to one grain per ounce, and this indicated the amount of glucose present. The high specific gravity was mainly due to excess of urea (3.1 per cent.), which formed a solid mass of crystals with nitric acid. The high specific gravity and the reduction of Fehling's solution, without a quantitative analysis, would naturally suggest that the urine must be highly saccharine, but, on the other hand, there had been no excess of urine, thirst, or other symptoms of diabetes. The process by which the natural creatinine is separated from the urine unchanged by heat or other violent methods occupies forty-eight hours; but the mere separation of the creatinine may be effected in a short time by the following method. Add to the urine one-twentieth of its volume of a saturated solution of sodium acetate and nineteen-twentieths of its volume of a saturated solution of mercuric chloride and filter. Boil the filtrate for five minutes and filter. Remove the excess of mercury by a few drops of strong liquor ammonias and again filter. The filtrate will be free from creatinine, and the amount of glucose, if any, can be determined, bearing in mind that the urine has been diluted by its own volume of liquid. If the loss by boiling has not been made up by the few drops of ammonias, this must be supplied by adding water before the analysis is made. It scarcely need be said that in analysing diabetic urine, when the amount of sugar is large, there is no need to take account of the small amount of reduction due to creatinine.

Some years since I published the fact that the urine of patients who are taking salicylate of soda is reddened by the picric acid test to a degree that might indicate from one to two grains of glucose per ounce. Cupric oxide is also reduced by the same urine as if by a small amount of sugar. I ascertained that the sodium salicylate has no reducing action upon either test. My son tested twenty-seven specimens of salicylate urine, and found that the reduction with picric acid ranged from 1/40 grain to 3/2 grains per ounce, the average being equivalent to 1/73 grain of glucose. He finds that the reducing agent is neither glucose nor an excess of creatinine. It is, no doubt, some product of the decomposition of sodium salicylate; but salicylic acid, which is found in the urine of these patients, does not reduce picric acid. These urines give a deep violet colour with perchorlioxide of iron, which would indicate the presence of some unusual sub-

stance in the urine even if it were not known that the salicylate was being taken.

I have lately examined the urine of a rheumatic patient who was taking fifty grains of sodium salicylate in twenty-four hours. The sp. gr. was 1.022. Absence of sugar was proved by the negative result of the Phenyl-hydrazine test. The picric acid test gave a colour equivalent to two grains of glucose per ounce. After separating the creatinine by the quick process before described, the reduction colour in the filtrate was reduced to 1/2 grain. The absence of creatinine in the filtrate was proved by the fact that no red colour occurred in the picroc of potash until the temperature reached the boiling point, and the presence of some product of salicylic acid in the filtrate, after the separation of the creatinine, was proved by the violet colour with perchloroloxide of iron. The indication of two grains to the ounce was due—0.8 grain to urinary creatinine, and 1/2 grain to some product of the decomposition of salicylic acid. Chlohar hydrate and chloroform, which are sometimes present in the urine, reduce cupric oxide, but have no action on the picric acid test.

My main object in the present communication has been to indicate some common sources of error in testing for sugar in the urine, and to recapitulate the main facts by which it has been conclusively proved that no sugar exists in the normal secretion. I may add that by means of the picro-saccharometer any practitioner may with ease, in the course of a few minutes, make an accurate determination of the amount of sugar per ounce or per cent. in a case of glycosuria.

Oxford and its University.

(Continued from p. 4).

PROGRESS OF KNOWLEDGE AT THE UNIVERSITY.

To trace the progress of knowledge at the universities is, in great measure, to follow the development of literature, science, and art in Europe. At Oxford, the dominant study was at first logical and philosophic, an attempt being made "to extract knowledge from consciousness by syllogistic reasoning, instead of gathering it from observation, experience, and research, mocking by its barrenness of fruit the faith of the enthusiastic student, yet training the mind to preternatural acuteness, and perhaps forming a necessary stage in the mental education of the race. The great instrument of high education was disputation, often repeated, and conducted with the most elaborate forms in the tournaments of the Schools, which might beget readiness of wit and promptness of elocution, but could hardly beget habits of calm investigation or paramount love of truth." Some of the greatest schoolmen—Duns Scotus, Bradwardine, and Ockham—were produced by Oxford, and Aristotelian speculation occupied a prominent position there.

Theology and law were the leading faculties, how-

* The quantities may be: urine, 34 = 340m; solution of sodium acetate, 12m; solution of mercuric chloride 28m.
† The various modes of testing for sugar in the urine will be found fully described in the author's "Medical Lectures and Essays," p. 798, etc.
‡ "Medical Lectures and Essays," p. 807.
ever, philosophy being less incisive, and physical science almost unknown, though the first rudiments of the latter and of mathematics had been brought to England by travellers, from the schools of Cordova and Bagdad. During the thirteenth century, Roger Bacon, whose reputed study existed, until recently, near Folly Bridge, studied the works of Aristotle, and devoted himself to the propagation of a knowledge of languages, geometry, arithmetic, and other subjects. After passing some time at the University of Paris, he returned to Oxford as a teacher, and attempted to extend scientific teaching there. But “scholasticism absorbed the whole mental energy of the student world. The temper of the age was against scientific or philosophical studies. The older enthusiasm for knowledge was dying down; the study of law was the one source of promotion, whether in Church or State; philosophy was discredited, literature in its purer forms became almost extinct.” Bacon persevered, nevertheless, and produced his “Opus Majus,” in which from grammar he passed to mathematics, under which term he included all that was known to him of physical science, and thence to experimental philosophy. The famous astronomer and alchemist held that “he who knows not mathematics cannot know any other sciences, and what is more, he cannot discover his own ignorance or find its proper remedies.” Bacon’s special study was optics, but he also brought geography, chronology, arithmetic, music, hydrography, geography, and astrology to some extent into systematic form.

The period of the Reformation saw the destruction of priceless libraries at Oxford, and the religious wars checked all progress for the time being. “Whatever life remained to the University was chiefly absorbed in theological study and controversy,” and “Oxford was turned into the cock-pit of the theological party.” Later, the Civil War caused a gap in academical history, and though, under Cromwell, excellent learning again abounded, the Restoration saw the colleges filled with a crowd of dunces. “Drinking, idling, and tavern-haunting were in the ascendant. Study as well as morality . . . was out of fashion” and, as a result, about this period science was driven from Oxford, a step which resulted in the foundation of the Royal Society of London.

The eighteenth century in its early part saw some intellectual life at Christ Church, but otherwise it was a blank in the history of the University. The colleges had become rich and their incomes were divided amongst a host of sinecurists, who were in many cases unconnected with the University; devotion to a life of study was rendered impossible, and idleness, intemperance, and riot were rife among the students. Candidates for examination, on bribing the University officer, were allowed to select their own examiners, whom they treated after the ordeal, and Lord Eldon is said to have taken his degree upon an examination in which he was asked two questions only:—“What is the meaning of Golgotha?” and “Who founded University College?” Of science at this time there was none.

The latest revival came about the beginning of the present century. Classics and mathematics became one more living subjects, and though the “Tractarian” movement for a time acted as a check, this was the end of the reign of scholasticism at the University. A Royal Commission being appointed to inquire into the state of affairs, the result was that religious tests were relaxed, the curriculum and examination system were liberalised, and “science, long an exile, was welcomed back to her home at the moment when a great extension of her empire was at hand.”

Another Commission, “acting on a still more recent Act of Parliament, has carried the adaptation of Oxford to the modern requirements of science and learning further than the old Commission, which acted in the penumbra of medieval and ecclesiastical tradition, dared. The intellectual Oxford of the present day is almost a fresh creation. Its spirit is new; it is liberal, free and progressive. . . . Again, as in the thirteenth century, the day of Grosseteste and Simon de Montfort, Oxford is a centre of progress, instead of being, as under the later Stuart, the stronghold of reaction.”

THE UNIVERSITY BUILDINGS.

The buildings of the University are mainly grouped around the Radcliffe Library in the centre of the city. This was founded in 1737, by Dr. Radcliffe, physician to Queen Anne, and is now used as a supplementary reading room of the Bodleian, and known as the Camera Bodleiana. Close by is St. Mary’s Church, the most beautiful of all the University buildings, where the University sermons are preached. The Convocation House is the hall of the University Legisature, and the place where the ordinary degrees are conferred. “Before each degree is conferred, the Proctors march up and down the House to give any objector to the degree—an unsatisfied creditor, for example—the opportunity of entering a caveat by ‘plucking’ the Proctor’s sleeve.” In the Divinity School adjoining, which dates from the Middle Ages, the examinations for degrees in theology are conducted. The Sheldonian Theatre is the scene of the annual commemoration of founders and benefactors. Here the inauguration of the Chancellor takes place, and honorary degrees are conferred. As in former days, the terra fílius or licensed buffoon used to enliven the ceremony, so now the occupants of the undergraduates’ gallery express their comments freely, and at times uproariously.

The University Council Chamber and the Registry are in the Clarendon, once the home of the University press, which has now migrated to larger premises in the north-west of the city. The Bodleian or University Library is one of the most important libraries in existence. It is entitled by law to a copy of every book printed in the United Kingdom, and is bound to preserve all it receives. Over the library is the Picture Gallery, containing the portraits, more or less fictitious, of early founders, and beneath used to be the schools or examination rooms, now replaced by the new buildings in the High Street. The Ashmolean Museum, close to the Bodleian, is now used for antiquities only. The other former contents of the museum and the medical library have been removed to the new University Museum on the north side of
The city, which by its existence may be said to proclaim the restoration of science at Oxford.

Less than sixty years ago there was not a single laboratory of any kind in connection with the University. A number of comparatively small endowments existed for professorships of chemistry, of anatomy and medicine, and smaller endowments for geology, mineralogy, astronomy, mathematics, and geometry. The Botanical Gardens, founded by Earl Danby in the seventeenth century, opposite Magdalen College, had been practically made by Dr. Daubeney, who devoted much time, money, and labour to developing them; and the nucleus of a fine herbarium also existed. Buckland and Lyell had also done much to overcome the neglect of natural knowledge by the University, but waves of indifference had swept over the place about the end of the last century, as already related. The revival came about 1830, but "left comparatively on one side the primary questions which belong to the unfolding knowledge of the nature and origin of organic beings and the unity of the material universe." In various ways enthusiastic workers in science were struggling to overcome the apathy with which their respective subjects were regarded, and encouragement was given to these pioneers by the British Association meeting at Oxford in 1847, which brought Faraday, Owen, and other distinguished scientists into personal contact with them.

The present advance in matters scientific seems to have come, to a great extent, as a result of the persevering efforts of followers of the medical art. The institution of practical classes in histology and embryology having proved a great success, suggestions were made to bring together in a single institution the different scientific collections belonging to the University, then scattered in rooms in various buildings, and so facilitate the study of natural and physical science. Ultimately, the new museum was erected, eighty acres of land near it being purchased to admit of future expansion and the development of a complete scientific institute, a working observatory was erected in the grounds, and steps were taken to organise a practical School of Medicine. A considerable part in the agitation was taken by Sir Henry W. Acland, Bart, D.C.L., F.R.S., etc., now Regius Professor of Medicine in the University of Oxford, and an esteemed honorary member of the Pharmaceutical Society. In company with others, he laboured hard to repair the mischief of two centuries ago, when physical science, driven from Oxford, found more congenial surroundings in London; and he now enjoys the gratification of seeing the University in the position of having regained its ancient opportunities for scientific work.

The new scientific institute contains excellent physical laboratories; the chemical department has not been stinted; geology, mineralogy, physiology, astronomy, geometry, mathematics, zoology, anatomy, and medicine receive proper attention, and this association of the workshops of the great departments of science has had its value intensified by the scientific library being transferred by the Radcliffe Trustees from the Camera Bodleiana to the new buildings.

Modern botany alone remains isolated, in the gardens near Magdalen Bridge.

The objects of the Museum, which may be regarded as the most comprehensive and complete institution in the world for the study of natural science, are thus summarised by Sir Henry Acland:—"First, to give the learner a general view of the planet on which he lives, of its constituent parts, and of the relations which it occupies as a world among worlds; and, secondly, to enable him to study, in the most complete scientific manner, any detailed portion which his powers qualify him to grasp . . . . For the illustration of Nature the student requires four things: first, a workroom, where he may practically see and work for himself; secondly, a lecture-room, where he may see and be taught that which by himself he can neither see nor learn, and, as an adjunct to these, a room for more private study for each; thirdly, general space for the common display of illustrative specimens, so placed as to be convenient for reference and comparison between all the different branches; and, lastly, a library, in which whatever has been done, or is now doing, in the science of this and other periods and countries, may be conveniently ascertained . . . . These varied requirements are here supplied."

It would thus appear that the determined efforts made by a number of Fellows of the University were fully justified by a large measure of success, and, in the course of some statements circulated in Convocation in 1876, it was pointed out that the University had entered upon a plan whereby its Department for Scientific Study and Research might in time become "unequaled, certainly unsurpassed, for convenience, completeness, and space for extension." The full results that may be produced by the study of natural science at Oxford remain yet to be seen, but that the professions whose foundations rest on such study have received a powerful impulse is clearly indicated by the present position of the medical faculty of the University, whose degrees rank second to none. That such progress may continue and be accelerated will be earnestly desired by all who have at heart the best interests of humanity.

In concluding this brief and necessarily imperfect account of the University buildings, which may be regarded as indicating the different high-water marks of knowledge during the past six hundred years, no more fitting words can be written than the passage in which Goldwin Smith sums up his interesting outline of the history of the University and the Colleges affiliated with it. "The buildings stand, to mark by their varying architecture the succession of the changeful centuries through which the University has passed. In the Libraries are the monuments of the successive generations of learning. But the tide of youthful life that from age to age has flowed through college, quadrangle, hall, and chamber, through University examination rooms and Convocation Houses, has left no memorial of itself except the entries in the University and College books. . . . Youthful effort, ambition, aspiration, hope, College character and friendship have no artist to paint them—at least as yet they have had none. But whatever of poetry clings to them is present in full measure here."
FRUIT JUICES AND SYRUPS.

A typical formula for preparing a concentrated fruit syrup may be found in the U.S. Pharmacopeia, namely, syrup of raspberry:

"Syrupus Rubi Idem."

"Syrup of Raspberry."

- Fresh, ripe raspberries, any convenient quantity.
- Sugar, a sufficient quantity.

"Reduce the Raspberries to a pulp, and let this stand, at a temperature of about 30° C. (86° F.), until a small portion of the filtered juice mixes clear with half its volume of alcohol. Then separate the juice by pressing, set it aside in a cool place, until the liquid portion has become clear, and filter. To every forty (40) parts by weight of the filtrate (which should not be allowed to remain, unprotected by sugar, more than about two hours) add sixty (60) parts of sugar, heat the mixture to boiling, avoiding the use of tinned vessels, and strain. Keep the product in well-stoppered bottles, in a cool and dark place."

This is the process of the German Pharmacopoeia, except that the latter directs 65 parts of sugar for every 35 parts of filtered juice. The temperature during fermentation prescribed by the U.S.P. should be maintained as nearly as possible. The French Codex directs fermentation to proceed at between 12° and 15° C. (54°-59° F.). Other fruit syrups may be prepared according to the same method. It may be explained that the fermentation is for the purpose of precipitating the pectin present, which otherwise interferes with filtration. The addition of alcohol is for the purpose of hastening this process, and also to aid slightly in the temporary preservation of the juice, to avoid acetic fermentation and fungoid growths. It is also believed that by this process of fermentation the aroma is more fully developed, especially in strawberry juice. Fermentation should proceed for about twenty-four to thirty-six hours.

It is important for the keeping quality of fruit juices that they be perfectly clear and bright, while in the case of the syrups, when bottled, all scum forming must carefully be removed by straining, having avoided all stirring while the liquid comes to a boil. Sometimes fermented fruit juices remain turbid and difficult to filter; to these a small quantity of skimmed milk may be added, which will be coagulated by the acids present, and thus act as a clarifier. Paper pulp will sometimes prove desirable for clarifying. Only the very best grade of sugar should be employed. The containers should be perfectly sterile and dry, the latter condition being insured by rinsing with alcohol.

When boiling hot syrup is poured into the bottles, the latter should stand on several thicknesses of cloth wet with cold water, to prevent cracking. Cork immediately, tie over, dip into sealing wax, and lay flat, and allow to cool off in that position; in fact, they should remain thus until opened, to insure preservation.

The different formulas printed below have been collected from various sources. The "Appert" process there mentioned is nothing but what is now called sterilising. The bottles are filled, allowing enough space for expansion of the contents when hot, the corks are inserted and securely fastened with twine. They are then placed into a vessel with cold water reaching up to their necks, standing on a false bottom or a layer of straw. The temperature of the water bath is gradually raised, and finally the boiling point maintained for 10-15 minutes. Removing from the bath, the tops are sealed over and the bottles allowed to cool in a reclining position. Some prefer to insert the corks only after sterilisation is complete. This involves less danger as to explosions, but is rather less reliable.

Syrup of Raspberry.—Continue the berries, place them in a vat, add 2 per cent. of sugar, and ferment the mass at a temperature of between 70° and 80° F. for three or four days until all pectin has separated and no more signs of fermentation are visible. Then express the juice, which allow to settle in a cool place for two days, decant carefully from the pulvulent pectin, and filter. Preserve the juice by Appert’s process, or convert into syrup by dissolving in 5 parts of the clarified juice 9 parts sugar, and heating to the boiling point.

2. A better and safer way is to add at once to the freshly bruised fruit 5 to 6 per cent. of alcohol, and then proceed as in the foregoing. This formula would seem to deserve preference.

3. Crush the raspberries in a glass vessel with a wooden pestle to a pulp, add to it 5 to 10 per cent. of cane or grape sugar, and allow the whole to stand, stirring occasionally. When the mass ferments the juice becomes clear, when it may be filtered and bottled, or converted into syrup.

4. Put six pounds of raspberries into a china bowl, with a quart of water, in which has been dissolved 2½ ounces of citric acid, and let it remain twenty-four hours; then strain, taking care not to bruise the fruit. To each pint of clear liquid add 1¼ pound of sugar, and stir until it is dissolved. Proceed as in No. 1. When the fermentation is nearly ended express the juice, add to every pound of the latter 1 ounce of the deodorised alcohol, set aside for one night, and then filter. Bottle the juice or convert into syrup.

5. Proceed as in No. 1. When the fermentation is nearly ended express the juice, add to every pound of the latter 1 ounce of the deodorised alcohol, set aside for one night, and then filter. Bottle the juice or convert into syrup.

6. Macerate the berries interspersed with sugar, 1¼ pound of sugar to 1 pound of berries, for twenty-four hours in a cool cellar, and then drain off the juice. Preserve the syrup by means of Appert’s process.

7. Add to the foregoing product some alcohol, or a little balsam nitre of lime. The flavour is not supposed to be impaired by the latter.

8. Pare fruit juice, 16 fluid ounces; dilute acetic acid, 1 fluid ounce; water, 7 fluid ounces; granulated sugar, 3 pounds. Dissolve the sugar without heat. Preserve in air-tight vessels in a cool place. The acetic acid is objectionable.

Syrup of Mulberry.—Mulberry juice, 1 pint imp.; sugar, 2 pounds; strong alcohol, 2½ fluid ounces. Heat the juice to the boiling point, and when it has cooled filter it. Dissolve the sugar in the filtered liquid with a gentle heat, and add the spirit.

Syrup of Strawberry.—Put 2 parts of strawberies
deprived of the calyx, without crushing them, into a large-mouthed jar; add to them 2½ parts of sugar, and frequently shake, keeping the vessel in a cool place. The sugar absorbs the juice, leaving the fruit shrivelled and tasteless, the latter being removed by means of a strainer without pressure. Mix the clear syrup with 20 per cent. of alcohol.

**Syrop of Cherry.**—Employ the black, sour variety. Crush the cherries, together with the stones, and follow the directions given in No. 2.

**Fruit Syrup for Lemonade.**—Raspberries, 1000 grammes; blackberries, 500; bilberries, 500; lemons, 3 fruits. Mash in a stone mortar, and add of cold water, 1500. Let stand for three days, or until fermentation has finished. Express and filter. In every 2500 dissolve citric acid, 40; and sugar, 4500. Boil up once in a copper kettle.—*Western Druggist.*

---

**HYDRASTIS CANADENSIIS.** *By Dr. J. Pohl.*

*Hydrastis canadensis* (Golden Seal) flourish in moist and shady woods in North America, and perishes when the woods are cleared. Seeds planted in the spring germinate in May, and produce seedlings with a dull yellow tap-root and deep yellow hypocotyledonary stem. In the second year four or five alternate cataphyllary leaves are developed, and also three foliage leaves, of which, however, only one is fully expanded. During the following years the plant continues to grow in a similar manner until the aerial axis finally produces a terminal flower at its apex. In this stage the plant possesses a rhizome with four or five cataphyllary leaves and short internodes. In the axis of these leaves buds are formed, of which the third one usually develops into a branch, which may either flower in the following year or may continue for some years to produce foliage leaves only. Branches may also be formed by adventitious buds on the roots.

The fresh rhizome is about two inches long and a quarter of an inch thick, branching, provided with numerous roots on its sides and lower surface, and deeply constricted at intervals into segments, each of which represents a year's growth. In the depressions the remains of the fibrovascular bundles of the foliage leaves can be observed, whilst the minute rings on the segments themselves are the scars left by the cataphyllary leaves.

In the fresh root (both in primary and secondary tissue) the berberine is contained exclusively in the vacuoles of the cells of the hypodermis and endodermis, and those of isolated parenchymatous cells lying closely applied to the xylem bundles; the vessels contain no berberine. In the rhizome the parenchymatous cells with berberine are extremely abundant immediately below the cork cambium and in the cortical parenchyma; they also occur scattered round the vessels. In the aerial axis the berberine is mostly confined to axially elongated parenchymatous cells near the fibrovascular bundles.

* Abridged from *Bibliotheca Botanica*, No. 29.

---

On anatomical grounds exception is taken to the opinion of Prantl that the genus *Hydrastis* is allied to *Paeonia*; it is more nearly allied to *Thalictrum*, as they both contain berberine, form a perennial rhizome, possess a caducous perianth, and show similarity in other respects.

The drug consists of the entire plant with the exception of the foliage leaves and part of the aerial axis; it contains rhizome, root, cataphyllary leaves and part of the aerial axis. The anatomical characters are identical with those of the fresh drug, but the localisation of the berberine is abnormal, inasmuch as it has permeated nearly the whole of the tissue.

Of all the substitutions, the rhizome of *Jaffcrum diphylla*, Pers., alone bears some similarity to *Hydrastis*. It is easily distinguished by the stone cells which occur in groups in the cortex, and as a ring in the pith, and by the absence of cells containing berberine.

---

**British Pharmaceutical Conference.**

**TITLES OF PAPERS TO BE READ AT THE OXFORD MEETING.**

The following is a provisional list of the papers promised:—

3. Conditions of Papain Digestion, by S. Ridel, D.Sc., Lond., F.I.C.
4. The Recovery of Residual Tinctures from Marcs, by R. H. Parker, F.C.S.
5. Note on Phosphorus Pills, by R. H. Parker, F.C.S.
8. Tincture of Iodine and its Analysis, by J. F. Liverseego, F.I.C.
12. Note on *Strychnos ignatia*, by F. Ransom, F.C.S.
15. Notes on Rhubarb, by Barnard S. Protter, F.I.C.
17. Animal Extracts, by C. E. Stuart, B.Sc.
SOCIETY OF CHEMICAL INDUSTRY.

The annual general meeting of this Society, to be held in Edinburgh next week, should have more than ordinary interest for the readers of the Journal, inasmuch as the President of the Society, Mr. E. C. C. STANFORD, is a pharmaceutical chemist and a member of the Pharmaceutical Society. Although now engaged in the management of chemical works in Scotland, Mr. STANFORD was formerly more closely connected with pharmacy, having been a student in the School at Bloomsbury Square, and for some time Demonstrator in the Society's Laboratory under the late Professor REDWOOD. Two years ago Mr. STANFORD was President of the British Pharmaceutical Conference, and in the address delivered by him at Edinburgh it was very evident that his interest in the well-being of pharmacy and pharmacists had not been weakened by the transfer of his activity to other pursuits.

The meeting of the Society of Chemical Industry, over which Mr. STANFORD will preside at Edinburgh, promises to be one of considerable interest. For the purpose of making arrangements for it, the Scottish section of the Society has formed a very influential committee, the chairman of which is the Lord Provost of Edinburgh, the Right Hon. Sir JAMES A. RUSSELL. Provision has been made to afford visitors the opportunity of inspecting many of the industrial establishments of Edinburgh and its neighbourhood, and also for excursions to places of interest in Scotland. A local ladies' committee has also been formed, to assist in the work of entertaining visitors, and on the occasion of the dinner on Thursday evening it is intended to hold a ladies' reception and conversazioni in the Victoria Hall.

The presidential address will be delivered in the Queen Street Hall at 11 a.m. on Wednesday, July 18. After the conclusion of business at the meeting, arrangements have been made to visit the local galleries and museums, Dalmeny Palace, Roslyn, Dalkeith Palace and grounds, or the paper works at Valleyfield and Eskmills. In the afternoon a garden party will be given by the Lord Provost, at his residence, Woodville, Canaan Lane, Granton. In the evening a reception and conversazioni will be held by the Lord Provost, Magistrates, and Council of the City of Edinburgh, in the Museum of Science and Art. On the following day a large number of works of various kinds will be open for inspection, in addition to Leith Docks, and at 1 p.m. a special train will convey visitors from the Waverley Station to Granton, in connection with a steamer proceeding to the Forth Bridge. On returning to Granton, Messrs. A. B. FLEMING and Co. will give a garden party at Roxton, and the special train will return to Edinburgh at 6 p.m. The annual dinner will be held the same evening, at 7.30 p.m., in the Waterloo Hotel. On Friday, excursions to Loch Tay, St. Andrew's and Perth, will be followed by a smoking concert in the Waterloo Hotel at 9 p.m.

WINE AS MEDICINE.

The suggestion that a chemist supplying the B.P. wine of iron might be placed in a position of liability to a fine for having infringed the Revenue Acts appears to involve the somewhat exaggerated and, as we think, unfounded opinion that the Inland Revenue authorities are disposed to interfere with chemists in the regular conduct of their business. In regard to the supply of wine, there is no statutory exemption from the necessity for a licence, even when the wine is to be used as medicine, but we are not aware of any instance in which the Board of Inland Revenue has sought to make the supply of wine as medicine amenable to the law. On the contrary, it has recognised the fact that certain forms of wine are medicinal preparations, and has consented to allow their supply by chemists without a wine licence, provided the wine be of such a nature as not to be capable of being used as a beverage. That position, while having regard for the object of the Revenue Acts, is in conformity with the evident intention of those Acts to distinguish between the supply of wine or spirituous liquors as a matter of ordinary trade and their reasonable supply as medicine. The same desire to distinguish between ordinary trade transactions and the proper prescription or supply of medicine is also manifested in the Medicine Stamp Act. The distinction thus drawn is an important one, and it appears to be the only ground upon which practical exemption from statutory provisions can be expected by chemists or medical men, and acceded to by the Inland Revenue authorities. The fact that an article is in the British Pharmacopoeia is a matter of little importance in this respect. Spiritus vini gallici is an article of the British Pharmacopoeia which may be dispensed in the form of the corresponding mistura, in the
ordinary course of the chemist's professional practice; but if the same preparation were supplied in a more literal manner there might be ample ground for regarding the practice so closely analogous to that of the publican as to involve equal necessity for a licence.

The difficulty experienced by the chemist arises from the mixed nature of his business. We do not apprehend that the exercise of its strictly professional part would ever be interfered with by the Inland Revenue authorities. But if the chemist, in the sale of wine or medicine, gives undue prominence to his position as a trader, and thus voluntarily brings himself within the scope of statutory provisions relating to trade, he cannot in that capacity expect exceptional consideration.

The mistake has been made of assuming—on the ground of an overstrained interpretation of statutory provisions—that exemptions intended to have a limited application might be extended to transactions of a purely trade character.

THE PROPOSED IMPERIAL BRITISH PHARMACOPEIA.

The editor of the Montreal Pharmaceutical Journal speaks with regret of the indifference with which this project has been received by Canadian pharmacists, and directs attention to a letter on the subject from Mr. J. E. D'Auionon, of Windsor, Ontario, in which he points out that the Ontario Pharmacy Act and the Dominion Inland Revenue Act recognise the British Pharmacopoeia, but there is some doubt whether it is, under the latter Act, really a compulsory legal standard for the preparation of medicines. From a practical point of view he mentions that many preparations of the B.P. are not used at all in Canada, and that some of those in use there are not in the B.P. Canadian pharmacists adhere pretty closely to the B.P., and the U.S.P. is chiefly followed in the case of preparations not mentioned in the B.P. Not long ago a committee was appointed by the Ontario College of Pharmacy to consider the establishment of a uniform pharmaceutical standard for the whole dominion, and to confer with committees of other colleges on this subject. In connection with that object a special Canadian Pharmacopoeia has been suggested, but Mr. D'Auionon does not think it would be practicable or advisable, and he is disposed to favour the idea of an Imperial British Pharmacopoeia providing, if necessary, for the particular requirements of Canada or other colonies in appendices. The Australasian Journal of Pharmacy also has an article on this subject, in which the project is favourably spoken of, but at present no steps appear to have been taken in regard to it by pharmacists in the Australian colonies.

The sub-committee of the Melbourne branch of the British Medical Association, appointed to draw up a report on the subject in accordance with the request of the General Medical Council, has held two meetings, and at the last Baron Sir Ferdinand von Müller drew attention to some of the indigenous Australian plants useful in medicine, especially that known as "pituri," and yielding duboisine. He also pointed out that while it has hitherto been a peculiarity of the British Pharmacopoeia to direct that various essential oils should be derived from plants grown in Great Britain, the climate of Victoria is particularly suitable for the growth and cultivation of most of the plants yielding such essential oils. He considered that it would therefore be desirable to obtain authority to make use of plants grown in the colony for pharmaceutical purposes. Red gum, now very extensively used, and the wattle bark, containing a larger amount of tannin than oak bark, were also mentioned as important items among the natural products of the Australian Colonies.

ADULTERATION OF DRUGS.

The Parliamentary Committee appointed last month to inquire into the subject of adulteration has now commenced its sittings, and it may be expected that the evidence given before it will lead to some important amendment of the existing Act. Though chemists, as a body, have not been to any considerable extent directly affected by the provisions of the Act, they are indirectly affected by the sale of impure or adulterated drugs and medicinal preparations of inferior quality, which is extensively carried on by persons who are not legally qualified chemists. The reports of the Local Government Board, in which the returns of public analysts are summarised, do not give any information as to the kind of shops where adulterated drugs have been sold and made the subject of prosecution under the Act, although there is reason for believing that such sales generally take place in the shops of unqualified persons. A case of this kind has recently occurred at Leeds, and from the report at page 37 it will be seen that ground existed for the warning recently given as to the sale of arsenical glycerin. This case will figure as one of conviction for the sale of an adulterated drug, and as the proper vendors of such articles are registered chemists, it will appear to reflect upon the mode in which they carry on their business. As Mr. Fairley justly stated, there is no reason why glycerin, sold as a drug, should contain arsenic. It ought never to do so, and it is the business of competent chemists to ascertain that neither that nor any other drug they sell is impure or adulterated. The grocer, who supplies commodities upon a very different footing, cannot be expected to ascertain whether such articles are of the
substance, nature, and quality required, and he has as little right to deal in them at all as he has to assume that no possible harm can arise from the presence of arsenic in glycerin.

PHARMACEUTICAL ORGANISATION.

It may be inferred from the proceedings at the last meeting of the Glasgow and West of Scotland Pharmaceutical Association that there is a desire to improve the practice of pharmacy in that city, and put an end to the unsatisfactory conditions which have prevailed there for many years. The remarks made by Mr. Anderson Russell, in bringing forward a motion containing suggestions for more effective organisation of those engaged in the business and better regulation of its exercise, do not admit of being commented upon, because the motion was only formally seconded, and the discussion of its details was adjourned. But we cannot do less than express our opinion that the motive underlying Mr. Russell's suggestions is eminently commendable, however much their practical achievement may be a matter for the future to realise. It may be that many will regard the ethical principle embodied in those suggestions as a purely sentimental idea, incompatable with the hard necessities of daily experience; but we trust that there will also be an adequate appreciation of the exceptional nature of the pharmacist's business, and of the corresponding necessity of its internal regulation from a professional point of view, in order to raise it above the lines upon which ordinary trade is conducted. That, as we understand Mr. Russell, is his aim, and in so far as his suggestions may be conducive to its attainment, they should meet with the hearty support of every registered chemist and druggist.

URINE TESTING.

An important point in connection with the detection of sugar in urine has been dealt with by Sir GEORGE JEFFERSON in a paper published in last week's Lancet, and as the subject is one of great practical interest to pharmacists, the paper has been reprinted in full at page 24.

PRESENTATION TO MR. E. F. HARRISON.

At the last meeting for the session of the School of Pharmacy Students' Association (see p. 37), the President, Professor Attyfield, on behalf of present and past members, presented to Mr. E. F. Harrison, Assistant-Lecturer in Chemistry, a watch and a framed photograph of the present students and staff of the School of Pharmacy, in recognition of his services in various capacities.

THE ARMSTRON CASE.

At the moment of going to press, the hearing of the further appeal in this case came on for hearing before the Master of the Rolls, Lords Justices Kay and A. L. Smith. The facts of the case have already been reported in the Journal (see III., p. 675) as well as the judgment delivered in the Derby County Court by His Honour Judge Dixie (Ibid., p. 768), and that of Justices Charles and Bruce (Ibid., p. 907) in the appeal of the defendants to the Queen's Bench Divisional Court. As it is impracticable to report the case without delaying the issue of the Journal, we can only state that it is proceeding, and that a full report will appear in next week's Journal.

ROYAL SOCIETY OF NEW SOUTH WALES.

This Society offers its medal and £50 for the best communication (provided it be of sufficient merit) containing the results of original work or observation upon each of the following subjects:—

Series XIV.—To be sent in not later than May 1, 1895.

No. 46.—On the Silver Ore Deposits of New South Wales.

No. 47.—On the Physiological Action of the Poison of any Australian Snake, Spider, or Tick.

No. 48.—On the Chemistry of the Australian Gums and Resins.

Series XV.—To be sent in not later than May 1, 1896.

No. 49.—On the origin of Multiple Hydatids in man.

No. 50.—On the Occurrence of Precious Stones in New South Wales, with a description of the Deposits in which they are found.

No. 51.—On the effects of the Australian Climate on the Physical Development of the Australian-born Population.

The competition is in no way confined to members of the Society, nor to residents in Australia, but is open to all without any restriction whatever, excepting that a prize will not be awarded to a member of the Council for the time being; neither will an award be made for a mere compilation, however meritorious in its way. The communication, to be successful, must be either wholly or in part the result of original observation or research on the part of the contributor. The Society is fully sensible that the money value of the prize will not repay an investigator for the expenditure of his time and labour, but it is hoped that the honour will be regarded as a sufficient inducement and reward. The successful papers will be published in the Society's annual volume. Fifty reprint copies will be furnished to the author free of expense. Competitors are requested to write upon foolscap paper—on one side only. A motto must be used instead of the writer's name, and each paper must be accompanied by a sealed envelope bearing the motto outside, and containing the writer's name and address inside. All communications to be addressed to the Honorary Secretaries, Messrs. T. W. E. David and J. H. Maiden, 5, Elizabeth Street, Sydney, New South Wales.

BRITISH PHARMACEUTICAL CONFERENCE.

Though the members of the Conference will each receive a copy of the "pink circular," describing the arrangements made by the local committee in connection with the Oxford meeting, it may prevent misapprehension and some inconvenience to state that the price of one of the books of tickets is more than usual. The No. 1 book admits to the receptions, luncheons, and smoking concert, and No. 2 covers the hall for the debates on the Thursday. The price of each book will be 10s. 6d., and, as stated last week, application for them should be made to the Honorary Local Secretary, Mr. Henry Matthews, 108, High Street, Oxford, not later than July 23.
Transactions of the Pharmaceutical Society of Great Britain.

DONATIONS.
At the meeting of the Library, Museum, School, and House Committee, held on Wednesday, the 11th inst., the Librarian and Curator presented the following report of donations to the Society's Libraries and Museums:

To the Library in London.
Royal Society of London:
Catalogue of scientific papers, vol. 10.
Royal Dublin Society:
Dr. Louis Planche, Montpellier:
Produits fournis à la matière médicale par la famille des apocynées, 1894.
Étude sur les produits de la famille des sapotées, 1888.
Les orchidées a coumarine le faham et ses succédanées, 1892.
Tableau des caractères des principales écorces de quinquinas américaines, 1894.

To the Library in Edinburgh.
Mr. Alexander Sutherland, Edinburgh:
Botanical terminology, by G. N. Lloyd, 1826.

To the Museum in London.
Professor H. H. Rusby, M.D., New York:
Specimens of genuine and false Cascara Sagrada, Saigon Cinnamon, American Acorus calamus rhizome, Peeled Male Fern rhizome, Liquorice root from Aliance, Calabria, and Anatolia, and Tomé bark from Bolivia.

Messrs. Evans, Leech, and Webb, London:
Large Specimen of the leaves of Pilocarpus micropus, and a specimen of uncured Vanilla from Maranham.

Mr. J. Whitehead, Bromley, Kent:
Specimens of medicinal fruits and roots collected in the Philippine Islands.

Messrs. Wilson, Smith and Co.:
Specimen of Kusonoki bark from Japan.

Mr. E. Bouquet, London:
Specimens of a wood and herb used as perfumes by the Kaffirs in Natal.

Mr. F. Coles, London:
Specimen of the root of Sandoeophalus esculentus.

To the Herbarium.
Professor H. H. Earby, M.D., New York:
Specimens of Erythroxylon bongii, of nearly wild and cultivated Erythroxylon coca, Dodonara viscosa, Manihot api, Argemone mexicana, Chenopodium quinoa, Krameria triandra, Piper angustifolium, and 7 varieties of the cotton-plant.
The Director, Royal Gardens, Kew:
Five specimens of Balsamodendron from the Bent Expedition to Hadramaut.

Baron P. von Mueller, Melbourne:
Twenty Australian plants.

To the Museum in Edinburgh.
Mr. Alexander Sutherland, Edinburgh:
Siamese of Assam, Catechu, and Santalum album, seeds of Gymnocarpos obovatus, Acanthocarpus occidentalis, and Trapa spinoa.

Messrs. Hodgkinson, Treacher, and Clarke, London:
Essential oil of asafeetida.

Mr. Alexander Strachan, Edinburgh:
Australian eucalyptus oil.

Mr. Thomas Stevenson, Bombay:
The Herbarium of British plants which gained the Society's bronze medal in 1883.

MAJOR EXAMINATION QUESTIONS.

BOTANY.

July 6.—Hours from 10 a.m. to 1 p.m.
1. Give the characteristics of the Natural Order Solanaceae, and contrast them with those of the Scrophulariaceae. Give their floral diagrams. Mention the important indigenous genera of the Solanaceae.
2. In what important feature do alfalfa differ from fungi? Give a short account of the life history of Claviceps purpurea.
3. Describe the structure of a living parenchymatous plant cell, by what means does it multiply? What chemical elements enter into the composition of the cell-wall, and the protoplasm? What change does the cell-wall undergo in the formation of cork?
4. Give an instance of a self-fertilized plant. Explain how this is prevented in (a) in dichogamous flowers, (b) in protogynous flowers, (c) in protogynous flowers, (d) in self-sterile flowers, and (e) in heterostylous flowers.
5. Examine and report upon the microscopic sections supplied.

MATERIA MEDICA.

July 6.—Hours from 2 to 5 p.m.
1. From what substances can Benzoic Acid be obtained? How may it be distinguished from Cinnamic Acid? What is its chemical relation to the purified oil of bitter almonds? Give tests for its purity and its chemical formula.
2. Discuss the B.P. process for the preparation of Tannic Acid. Give tests which shall ensure the purity of the Acid. State what chemical relation it bears to Tannin. How may it be distinguished?
3. How can Sulphate of Quinidine be detected in Sulphate of Quinine? Give the physical, chemical, and optical characters of the two substances.
4. What is Sparteine? How can it be obtained? Can crystallizable salts of it be formed?
5. How can Osmium Tincture be obtained? Discuss its formation and chemical constitution. What is its specific gravity?

CHEMISTRY.

July 7.—Hours from 10 a.m. to 1 p.m.
1. What are the distinguishing characters of the nitro-phenols? Give a detailed account of the process you would adopt for their preparation in a pure state.
2. How may the composition of ammonia gas be demonstrated?
3. Give the constitutional formula, methods of preparation, and characters of the dibhydroxybenzenes. By what means may hydrocarbons of the CnH2n+2 series be converted into those of the CnH2n+1 series? Give an example.
4. What weight of oxygen is required for the complete combustion of one gramme of olefin gas? What volume would the resulting mixture occupy at 200° C. and 760 m.m. pressure?

PHYSICS.

July 7.—Hours from 2 to 5 p.m.
1. Write a short paper on magnetic induction, describing and explaining experiments in illustration.
2. Define the following expressions:—Magnetic field, magnetic moment, and intensity of magnetisation of a magnet.
3. What is double refraction? Give an example.
4. Describe fully the construction of Rutherford's maximum and minimum thermometers.
5. Explain briefly the principles of the following processes in ordinary "silver" photography:—
(a) "Exposure of the plate."
(b) "Developing."
(c) "Fixing."
(d) "Printing."
(e) "Toning."

FIRST EXAMINATION QUESTIONS.

JULY 10, 1894.

LATIN.

Time allowed—from 11 a.m. to 12.30 p.m.

I. (For all Candidates.) Translate into Latin:—
1. The gift delights the brave sailor's children.
2. The cities were being fortified with high walls.
3. It is the duty of good citizens to obey the laws.
4. We eat to live; we do not live to eat.
5. Who is there who does not pity those who have been falsely condemned to death?

II. Translate into English either A (Caesar) or B (Virgil).

Candidates must not attempt both authors.

A. CAESAR.

1. Haec aestem tempestrum Caesar mandata referuntur, et legati ab Aedulis et a Treviri veniabatur: Aedui, quaestum, quod Harudes, qui nuper in Galliam transportat esset, fines eorum popularentur; sese ne essetuddin quidem datis pacem Aequitiad redimere potueret; Treviri autem, pagos centum Suevorum ad ripas Rheina transire consuerat; his praesess Nanaum et Cimmerium fratres. Quibus rebus Caesar vehemens commotus maturendum sibi existimavit, ne si nova manus Suevorum cum veteribus copias Aequitiae esse conjunxisset, minus facili resiust possent.

2. Eorum satisfactione accepit, et inimico exquisito pridivitassium, quod ex aliis et maxime fidem sesebat, ut millium amplius quinquaginta circuitu locis spatius exercitum duceret, de qua vixilla, ut dixerat, profectus esset. Septimo die, quum iter non intermittet, ab exploratoribus certior factus esset, Aequitiae copias in nostris millibus passuum IV et XX abesse.

Grammatical Questions.

(For those only who take Caesar.)

1. Give the genitive singular, and the gender, of the following nouns:—mare, fur, poema, nix, vox, portus, nata, saepe.
2. Give the principal parts of all the verbs in Paragraph 2.
3. Parse fully—Eorum satisfactione accepit, et sum inter non intermittet (Par. 2).
4. What is meant by the Sequence of Tenses? Give, in illustration, three sentences in English and Latin.

B. VIRGIL.

2. At Venus obscurior gradiens aere saepet. Et multo nebulose circa des fuit amictus, Cernere ne quis eis nec quis contingere posset Motivere moram aut venienti posse causar. Ipsa Paphum sublimis abit, sedesque revisit Laeta sonat, ut quantumque Sabeo Ture calen arae, sertisque recentibus balant.

Grammatical Questions.

(For those only who take Virgil.)

1. Give the genitive singular, and the gender, of the following nouns:—mare, fur, poema, nix, vox, portus, nauta, saepe.
2. Give the principal parts of all the verbs in Paragraph 1.
3. Parse fully—At Venus obscurior gradiens aere saepet (Par. 2).
4. What is meant by the Sequence of Tenses? Give, in illustration, three sentences in English and Latin.

ARITHMETIC.

Time allowed—from 12.30 p.m. to 2 p.m.

[The working of these questions, as well as the answers, must be written out in full.]

1. What is the cost of telegraphing to a distance of 3800 miles a message consisting of 300 English and 150 Persian words, at the rate of 4s. per mile for every 50 English and 4d. per mile for every 30 Persian words.
2. If £1 is 1/4 of an estate be worth £300, what will be the value of 2/3 of the estate?
3. Express 4/3 of £5 of 9 days 16 hours + 0390625 of 10 days 16 hours as the decimal of 23½ days.
4. A bankrupt's dividend being 11s. 11d. in the £, how much is lost by a creditor who has sold him 17 cwt. 0 qr. 0 as. goods at £1 2s. 6d. per cwt.?
5. A cistern is 4 metres long, 24 decimetres wide, and 80 centimetres deep; find its capacity in cubic metres.
6. If £1 5s. per cent. would be gained by selling 121 lbs. for £21 11s. 10d., at how much per lb. must it be sold to gain 15 per cent.?
7. Find how much money must be invested in a 4 per cent. stock at 104½ to produce an income of £156 18s.

ENGLISH.

Time allowed—from 3 p.m. to 4:30 p.m.

1. Analyse:—
   "Far above it on the steep,
   Ruined stands the old chateau,
   Nothing but the donjon keep
   Left for shelter or for show."

2. Parse fully the following words in the passage above:—Far, Ruined, Nothing, but, Left.
3. Explain the meaning of the following prefixes, and write words formed by means of them:—a-, an-, anti, dis, ex, etc.
4. In the following passage supply the necessary capital letters, and put in the stops and inverted commas where necessary:—when thorburn held forth the sword all the guardsmen praised it and said it was an excellent weapon but it had one grievous blemish for there was a notch in the edge oh said thorburn that notch is no blemish at all it is a memorial of one of my greatest achievements what was that asked one of the varangians.

*5. Write a short essay on any Town or Book with which you are acquainted.

JACOB BELL SCHOLARSHIPS, 1894.

EXAMINATION QUESTIONS.

Time allowed—Three hours (11 to 2).

In awarding marks the neatness and legibility of the writing will be taken into account.

LATIN.

1. Translate into English:—
   Saepe fugam Danai Troia cupiunt reaffict
   Moliri, et longo fossa discernere bolio;
   Factisanteque utinam salve illos apera ponte
   Intercursit hiems, et terruit Auster centes.
   Praeclipe, quam iam hic trahiss contextus actius
   Staret equus, tote sonnerunt asthere nimihi
   Suspensae Eurypylym actitantem oracul Phoebi
   Mittimus; itaque adytis haece tristis dicta reportat;

*This must be attempted by every candidate.
"Sanguine placentis ventos et virgine caesa, 
Quam primum illas, Dann, venisit ad oreis; 
Sanguine quaerendi redditis, animaque litanum 
Argyrica."

2. Translate into English:—
(a) Mitte collutorium, cum tanto aquae calidae utendum. Utere collyrio, noote maneque, si non frequentius usurpando. Guttes tres subinde instillandae.
(b) Distillatio a balneo arenae leni calore et vas excutiens bene refrigerando, daceo circiter unciae septem transierint, quae in vaso vitreo epistomio vitreo clauso serva.

3. Parse placætis, contextus, scitament, and give the principal parts of these verbs. (Question 1.)
4. Translate into Latin:—
(a) Caesar sent messengers to the Lingones to tell them not to help the Helvetii with corn or anything else.
(b) Having by his iniquitous sentences filled the prisons with the most industrious and deserving of the people, he then proceeded to order numbers of Roman citizens to be strangled; so that the exclamation "I am a Roman citizen!" which has often in the most distant regions, and among the most barbarous people, been a protection, was of no service to them.

ENGLISH.
1. Parse fully:—
"Methought I heard a voice cry, 'Sleep no more!'"
2. Write a short essay on one of the following subjects:
(a) "Variety's the very spice of life That gives it all its flavour."
(b) "Content is a kingdom."
(c) The Educational value of Examinations.

ARITHMETIC.
1. Two numbers have for their Greatest Common Measure 637, and for their Least Common Multiple 18795. What must the greater be, if the less equals 105 times
\[ \frac{27}{49} \times \frac{81}{8}\]
2. Add together ·60625 of £1, ·42857 of 14s. 10½d., and 2½ of 3½ of £5 6½d.; and express the result as the decimal of 27 shillings.
3. If with 53-46 Kilog. of thread a man can weave 251 metres of linen 1'14 metres broad, how many metres of linen 05·12 broad can he weave with 75-6·8 Kilog. of thread of the same quality?

FRENCH OR GERMAN.
The candidate is at liberty to choose either French or German, and is not required to show a knowledge of both. Marks will be awarded for one only.

French.
1. Translate into English:—

2. Translate into French:—
Edward the Third had spent a long time in trying to take the city of Calais, and when the citizens, almost starred, offered to surrender to him, he at first declared he would give no quarter; but at last he said that, if six of the chief citizens came to him bare-footed and bareheaded, with ropes about their necks, he would hang them, but spare all the rest.

German.
1. Translate into English:—

2. Translate into German:—
Edward the Third had spent a long time in trying to take the city of Calais, and when the citizens, almost stared, offered to surrender to him, he at first declared he would give no quarter; but at last he said that, if six of the chief citizens came to him bare-footed and bareheaded, with ropes about their necks, he would hang them, but spare all the rest.

CHEMISTRY.
What weight of phosphoric anhydride can be obtained from 100 litres of oxygen?
\[ P = 81; O = 16. \]
How are the oxides of carbon made? Describe their chemical and physical properties.

PHARMACY.
Write a short account of the chief ointment bases. Define the following:—Dialysis, Distillation, Sublimation, Rectification, Percolation. Name some products obtained by these processes.

BOTANY.
Describe in technical terms any common flower with which you are familiar.
Define the following:—Epiphyte, Parasite, Biennial, Phloem, Rhizome.

Proceedings of Societies in London.

BRITISH PHARMACEUTICAL CONFERENCE.

A meeting of the Executive Committee was held at 17, Bloomsbury Square on Wednesday, July 4.

Present: Mr. N. H. Martin (President), Mr. Martin-dale (Vice-President), Mr. Moss (Treasurer), Messrs. Holmes and Farr, Mr. H. Mathews (Hon. Local Secretary), Messrs. Naylor and Ransom (Hon. General Secretaries), and Mr. Nightingale (Assistant Secretary).

Letters were received from Messrs. Atkins, Hayes, Gerrard, and Payne, regretting their inability to be present.

The minutes of the last meeting were read and confirmed.

A suggested list of officers for recommendation to the general meeting, for election for the ensuing year, was considered.

The place of meeting for 1895 also received some consideration.

The chairman of the Formulary Committee announced that the new edition of the "Unofficial Formulary" was now in type, and would be ready for presentation at the general meeting.

Mr. Mathews reported that the arrangements for the Oxford meeting were nearly completed.

Eleven gentlemen having been duly nominated were elected to membership.

ROYAL MICROSCOPICAL SOCIETY.

A meeting of this Society was held on June 20, Mr. A. W. Bennett, M.A., F.R.S., in the chair.

Dr. J. E. Talmage described his method for mounting and staining the brine shrimp, Artemia salina.

Dr. W. H. Dallinger called attention to a stereoscopic photomicrograph of injected muscle which had been presented by Dr. W. C. Borden.

Dr. Dallinger exhibited and described a new form of mechanical stage for the microscope which had been produced by Messrs. Swift.

Further remarks were made by the Chairman, Messrs. Comber, Swift, More, and Beck.

Mr. J. H. Harvey described a method of mounting opaque objects so that they could be moved in all directions whilst under examination.

Mr. T. Comber read a paper on the unreliability of certain characters generally accepted for specific diagnosis in the Diatoms.

A discussion ensued in which the Chairman, Professor F. J. Bell, and Mr. J. J. Badcock took part.

Professor Bell gave a résumé of Mr. F. Chapman's sixth paper on the "Foraminifera of the Gault of Folkstone."
SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The last meeting of the session was held on Thursday, June 23, Professor Attfield, F.R.S., President, in the chair.

The Secretary read the following:

ANNUAL REPORT OF THE EXECUTIVE COMMITTEE.

"Your Executive Committee, appointed by vote of the Association at the commencement of the session in November last, have met and transacted business as follows:

"At a meeting on December 7, 1893, the Committee received the Secretary's report that the usual nominations and voting papers had been laid at the commencement of the session to all members who had paid their subscriptions; also that the papers and reports of the previous session had been copied in type, and the bound copy had been presented to the Library of the Pharmaceutical Society.

"The following were appointed by your Committee as reporters on the sciences allied to pharmacy:—Pharmacy, Mr. W. Moore; Botany, Mr. E. Goulding; Materia Medica, Miss B. Shove; Physics, Mr. T. Tickle; Organic Chemistry, Mr. C. S. Ellis; Inorganic Chemistry, Mr. H. Garnett; Analytical Chemistry, Mr. R. H. Jones.

"At a meeting a grant of seven shillings and sixpence from the Research Fund was made to Mr. C. E. Robinson to defray the expenses of his paper on 'Commercial Jalsas and Jalapins,' and at a meeting on January 26, 1894, a grant of seven shillings was made to Mr. H. B. Cox to meet the cost of the ether used in his experiments with tobacco.

"On April 23 the Committee met and arranged suitable localities and dates for botanical excursions on Saturday afternoons; where practicable those were made to coincide with the excursions of the cricket club, separate excursions being made to Chislehurst and, by invitation of the President, to Watford. The members joining these excursions have been fewer than in the two previous years during which they have been in existence. The membership of the Association has also fallen somewhat in comparison with the past two or three sessions; there are now sixty members and the average age of the members is in the neighborhood of twenty-six, twenty-seven and eight respectively last session. The attendance at the meetings has, however, been good, and members have contributed freely to the papers and discussions. The number of meetings, including to-night's, has been fourteen, and the total attendance 286, making an average of slightly over twenty at each meeting.

"The following twenty-seven communications have been read:—Introduction to the Address, by Mr. F. Ransom; 'Bees,' by Mr. A. T. Hill; 'Commercial Jalsas and Jalapins,' by Mr. C. E. Robinson; 'Note on a New Species of Cascarilla,' by Mr. A. W. Southall; 'Botany and Botanists,' by Mr. T. A. Henry; 'Tobacco,' by Mr. E. H. Cony; 'Gascoigne,' by Mr. E. E. N. St. C. V.; 'Linseed,' by Mr. H. A. Potter; 'Molybdenum and its Reactions,' by Mr. A. Lander; 'Report on Analytical Chemistry,' by Mr. A. Lander; 'Tone and its Compounds,' by Mr. C. J. Taylor; 'Relation of the Chemist to the Practitioner,' by Mr. E. J. Elston; 'Leather, Its Preparation,' by Mr. A. Lander; 'Report on Leather Manufacture,' by Mr. A. C. Bateson; 'Materia Medica of the Garden,' by Mr. H. A. Potter; 'Report on Pharmacy,' by Mr. W. Moore; 'Protoplasma,' by Mr. E. Goedling; 'Malt and Malting,' by Mr. A. E. Skinner; 'Aquatic Plants,' by Mr. C. E. Ashby; 'Report on Organic Chemistry,' by Mr. C. S. Ellis; 'Leather and its Preparation,' by Mr. E. G. Gaul; 'The Flowers of the Month,' by Mr. E. E. Dolbear; 'Photo-Micrography,' by Mr. A. Lander; 'Capillarity,' by Mr. T. Tickle; 'Early Chemistry,' by Mr. H. Burrows; 'Report on Inorganic Chemistry,' by Mr. H. Garnett.

"These papers are being copied in type and bound for presentation to the Pharmaceutical Society's Library, as in previous sessions.

"The Treasurer's accounts, to be presently audited, show that the receipts from members' subscriptions and interest on invested funds have amounted to £8 11s. 6d., and the expenditure to £8 19s. 5d., leaving a balance of £1 12s. 3d. to be added to the Research Fund. Grants to the extent of 14s. 6d. have been made from this fund, leaving a balance of £24 17s. 9d."

Mr. H. B. Cox and J. W. Ward were then appointed to audit the Treasurer's accounts, which they reported to be correct. The adoption of the report was then upon moved by the Chairman, seconded by Mr. H. Burrows, and carried unanimously.

A vote of thanks to the President, officers, and reporters for their services was proposed by Mr. Dyer, seconded by Mr. C. J. Taylor, and carried by acclamation.

The President then, on behalf of present and past students, presented to Mr. E. F. Harrison, in view of his approaching departure, a watch and a large framed photograph of the students and staff of the School, in recognition of his services as Assistant Lecturer in Chemistry, and in other capacities in the School. Mr. Harrison expressed his gratification at this evidence of the cordial relations which existed between the students and himself, and thanked them heartily for their present.

The meeting then terminated.

Scottish Transactions.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

The fourth botanical excursion of the season took place on Wednesday, July 4, to Brae Burn, by suburban train to Morningside at 6 a.m. The weather was fine, and a large number of plants were collected.

It was unfortunate that there was a very small attendance of members, for the station offered very good opportunities for practical field work.

Parliamentary and Local Proceedings.

PROCEEDINGS UNDER THE SALE OF FOOD AND DRUGS ACTS.

ABSENCE IN GLYCERIN.

At the Leeds City Police Court, on July 6, before Mr. Vincent Thoms, the Deputy Stipendiary, John Trimmie, trading as Hobson and Trimmie, grocers and drysalters, Kirkstall Road, Leeds, was summoned at the instance of the Leeds Corporation for a breach of the Food and Drugs Act. Mr. Bairstow, instructed by the deputy town clerk (Mr. C. C. Jolliffe), prosecuted, and the defendant appeared in his own behalf.

In opening the case for the prosecution Mr. Bairstow said that glycerin which contained arsenic was being extensively sold in Leeds. For the purpose of testing the matter purchases were made from time to time. On the day in question Charles Gill, the assistant of the Inspector of Food and Drugs (Mr. Walker), went to the defendant's shop and asked for a bottle of glycerin from defendant's assistant. The latter asked, "Is it for inward or outward application?" and Gill replied, "I want it for a friend." He was then sup-
plied with a pound bottle of glycerin, and Walker, entering the shop, informed him of the reason for the purchase in compliance with the conditions of the Act. The assistant refused to take advantage of the offer to take a portion of the glycerin for separate analysis. The glycerin was afterwards found to contain two grains of white arsenic per lb. Mr. Bairstow went on to refer to the section of the Act under which the proceedings were taken, and in reply to the magistrate said that he did not suppose anybody would take a pound of glycerin, but he did say that arsenic in the smallest quantities was injurious to human beings, and that the dealer would necessarily do any harm, but if a person took home a bottle and allowed his children to take it great risk would be run of injury to health. If a grown-up person took the glycerin he would possibly have to take a considerable quantity before he was seriously injured. His argument was that if a person went into a shop and asked for glycerin he had a right to expect pure glycerin and nothing else, especially when it was labelled "pure glycerin," as was the case in this instance. Mr. Bairstow, continuing, said that there was no doubt that in this case the article supplied was to the prejudice of the purchaser, and with respect to the price, substance, nature and quality demanded by him.

The Magistrate: Was there any intimation on the bottle that it was for outward application only?

Mr. Bairstow, in reply, said that that was not the case, and that if the defendant had adopted that course there would be an end to these prosecutions against him.

Evidence of the sale having been given, Mr. Scattergood, surgeon, and Dr. Cameron, medical officer, spoke to the danger in the sale of glycerin containing two grains of arsenic to the pound.

Mr. Fadley, city analyst, said he had analysed the glycerin in question, as well as other samples. Most of the samples were absolutely pure, with the exception of the defendant's, and there was no reason why there should be arsenic in glycerin at all. He was not aware that the process of procuring glycerin without arsenic varied the price of glycerin.

The Corporation Inspector, in reply to the Deputy Stipendiary, here stated that some of the samples that he had bought, and purchased at a penny less than that paid for the glycerin in question, had been proved to be without arsenic.

The defendant, addressing the Court, contended that he had not been fairly dealt with, inasmuch as when his assistant asked the purchaser if he wanted the glycerin for outward or inward use the purchaser did not answer the question, but evaded it by saying that he wanted it for a friend. That, he submitted, was a trap that had been unfairly laid for him. His defence was that the drug had been sold for outward use, and as such it was, he submitted, perfectly suitable. The glycerin was not sold to the prejudice of the purchaser, as it was sold for outward use. He felt sure that whatever impurity there might be in the glycerin was so small that no possible harm could arise from its outward use.

The court decided that the case had been proved against the defendant, and ordered him to pay a penalty of £3 and costs.—Yorkshire Post.

**POISONING CASES AND INQUESTS.**

**Supposed Poisoning by Infants' Cordial.**

An inquest was held before Mr. D. Wightman, coroner, at Sheffield, on the body of Jane McKay, aged four days, who had died from the effects of a dose of infants' cordial, administered inadvertently.

Dr. Mathews said he was called in on Wednesday morning at one o'clock, when the child was in a state of coma. He then formed an opinion that she was suffering from a narcotic poison, probably a preparation of opium. He stayed with her four hours, keeping her alive by artificial respiration. The father of the child told him she had been given a cordial and showed him a small bottle. He tasted the cordial, but could not detect the presence of opium. Any dose of opium would be dangerous for a child of the age of deceased.

Replying to the coroner, witness said the child lived so long that she had been very minute, and he did not think a chemical analysis would reveal the presence of opium. In his opinion the child died from a narcotic poison, although it was possible that she might have died from an affection of the kidneys.

Sarah Wright, a widow, said she gave the child some of Ibbotson's cordial on Tuesday night. The stuff had been bought two months previously from Mr. Percy Carr, chemist, Ecclesall Road. Not more than four drops were given the child, who appeared to get worse.

The coroner said he was satisfied that a post-mortem examination would not assist the jury in any way. There were very few of these collars that did not contain opium. He did not think they would come to the conclusion that the woman intended to harm the child, as her conduct was undoubtedly actuated by kindness towards the mother. She no doubt gave the cordial to the child inadvertently, without any felonious intent. These children's mixtures were very nasty things, but they were widely used.

The jury returned a verdict "that the child died suddenly, death probably being accelerated by a dose of infants' syrup, administered by Mrs. Wright, but without any felonious intention."—Sheffield Telegraph.

**Reviews and Notices of Books.**

**Handwörterbuch der Pharmacie:** Praktisches Handbuch für Apotheker, Ärzte, Medizinalbeamten und Droguisten. Edited by A. Brestowski. In 24 parts at 2 M. 40 Pf. each. (Vienna and Leipzig: Wilhelm Brunmüller).

The publication of any work by which, with a minimum expenditure of time, a maximum of reliable information can be acquired, must of necessity be cordially welcomed. An excellent work of such a kind is the 'Dictionary of Pharmacy' now in course of publication under the auspices of A. Brestowski, assisted by a number of collaborators well-known in scientific circles. As the editor observes in his announcement, the rapid development of the numerous branches of the sciences with which pharmacy is connected renders it absolutely impossible for any one man to keep abreast of the advance in all. The object of the 'Dictionary' is to remedy easily and quickly the deficiencies thus necessarily occurring, and it is intended not only for pharmacists, but for pharmaceutical students, physicians, and others. The work is to be divided into two volumes, a first or general and a second or special part. The first volume, which is now appearing, is to be completed in about 24 parts.

The work appears to fulfil admirably the object of the editor. By the strict alphabetical arrangement of the matter, the numerous synonyms, and above all the distinct heavy type in which the titles
are printed, reference is immensely facilitated. Each article is well brought up to date, and the information conveyed in it will be found reliable, concise, and sufficient, three qualities the value of which for busy men can scarcely be over estimated. Of particular importance to pharmacists must be considered the prominence given to the newer synthetic remedies. For example, under "antipyrin" will be found a short account of its probable constitution, its preparation by Knorr, and that of an isomeric, if not identical, body by Böhringer, with the principal tests of identity and purity. Further, a number of substances with which it is incompatible and compounds into the composition of which it enters are indicated. The use, dose, and detection in the urine terminate an article included within the limits of three columns. Acetanilide is treated of in a similar but more concise manner, and the ten columns devoted to "proteids" contain a lucid description of the various bodies included under that name. Under "Mineral Waters" the chief springs and their properties are noticed, whilst a short account of the principal methods of food analysis occupies fifteen columns. Coffee and coffee substitutes, and wine and wine analysis, are treated of at length. The absence of Illustrations is much to be regretted. Some articles include a short bibliography of the principal works bearing on the subject, an addition of great and obvious value which might with advantage have been more generally introduced. Although the "Dictionary of Pharmacy" appears close upon the heels of Moeller's "Real Encyclopaedia of Pharmacy," it is a work quite distinct in character, and will be preferred by those who desire concise and later information; the latter advantage will probably be still more prominent in the second volume. Type and paper are all that could be desired, and the "Dictionary of Pharmacy" can be strongly recommended to pharmacists who wish to provide themselves with a reliable work of reference on the lines that have been indicated.

Correspondence.

The Revision of the British Pharmacopoeia.

Sir,—In answer to the letter of "Scotus," as speaking by experience, we have found that the average quality of English honey is so infinitely superior to the lower priced average Irish honey, it would be vexatious if there were no distinction.

Bristol. A. and J. Warren.

Sir,—My attention has been called to an error in the suggested form for inst. camph. co. in my letter published in the Journal for June 30. Ac. bens. 2 fl 1/2. I should read 3 fl 1/2. I think the mistake must have been the printer's, as 1 fl was certainly intended. If vin. ferri requires a licence for its sale, would it not be better to sell for steel wine vin. ferri citr., which contains very nearly 2 per cent. ? And if a Pharmacy Act Amendment Bill ever gets into Parliament, two or more quinquennia, provide that no registered chemist should be required to have a licence for the sale of any P.B. preparation?

Kettering. J. F. Thurstfield.

The Pharmacy Acts in Glasgow.

Sir,—As a likely means of securing fuller observance of the Pharmacy Acts, particularly in Glasgow, I made a suggestion at the recent meeting of our local Association, intended not so much for it as for the Pharmaceutical Society. From the reports published I think it unlikely that my meaning can be fully understood. It was suggested that an experiment might well be made in Glasgow, the experiment to consist of compiling a list of all the drug shops in the city, arranging it so that the condition of each, so far as qualification was concerned, would be seen at a glance. The arrangement might be under three headings: (1) Shops in which there is no qualified person (such shops exist); (2) where there is one only; and (3) where there are two or more qualified persons. The list could be revised from time to time. There should be no secrecy about such a thing being done; indeed, therein lies one great reason for its success. Knowledge of being most offenders or as he was taken in conjunction with a few prosecutions, if necessary, would have a much greater deterrent influence than prosecutions by themselves, and the same knowledge should tend to cause persons to give the necessary information regarding the conduct of their business when asked to make the list complete. It is undoubtedly a hardship when persons here and there are prosecuted and punished as "black sheep," while it is the custom of their immediate neighbours to continue committing the same offence with impunity. What person under such circumstances could without quality of conscience give specific information regarding individual offenders? Small wonder is it that persons being prosecuted turn their thoughts on "who has been the informer?" rather than on their own misdeeds, and the Pharmaceutical Society is in turn regarded as a persecutor. Full and methodical enforcement of the above was most calculated to cause the action of the Society to be viewed as dignified and just even by offenders themselves. It would also be most economical. What I have suggested might well be undertaken by the local societies, and no doubt local associations would support them. By all means let us have demonstrated to all both the strength and weakness of the Pharmacy Acts. My experience here is that complaint is general in the trade against both the Society and Pharmacy Acts. Those complaining have already esta

THE PREPARATION OF SUPERFATTED SOAP.

BY C. D. MOFFAT.

In preparing neutral and superfatted soap according to the formula given by Mr. Johnson in the *Pharmaceutical Journal* of June 16, I found that on applying to the products the calomel test recommended by him there was, in both instances, a blackening of the calomel, indicative of the presence of free alkali, and showing that the proportions of alkali used were too large for producing even a neutral soap.

As Mr. Johnson mentions that he operated with the materials at his disposal, and does not state the actual strength of the caustic potash he used, it appeared probable that a difference in this respect might be the cause of the different result I had obtained.

In order to clear up this point, the saturating power of the lard I had employed was determined by heating 1 gramme of it with 20 C.c. of alcoholic solution of potash in a steam bath until saponification was complete, and then titrating the excess of alkali with standard hydrochloric acid (1 C.c. = 0·06814 Grm. KOH), after adding alcoholic solution of phenol-phthalein. The quantity of acid required to discharge the pink colour was 9·7 C.c. and that required by 20 C.c. of the potash solution was 11·3 C.c., the difference of 2 C.c. (=0·06814 x 2 = 0·13628 Grm.) representing the quantity of potassium hydrate required to saponify the lard.

This result corresponds very closely with the data given by Köttstorfer for the saturating power of lard. According to that authority the fat acid of 1000 parts of lard is saponified and neutralised by from 186·4 to 188·8 parts of potassium hydrate. Hence it is evident either that the quantity of alkali given in Mr. Johnson’s formula was too large for producing a neutral soap, or that the caustic potash he used must have been very weak.

On testing the caustic potash I had employed, it was found to contain 81·7 per cent. of potassium hydrate. Consequently, the quantities of potassium hydrate that were used in preparing neutral and superfatted soap according to Mr. Johnson’s formula and the quantities actually requisite were:

<table>
<thead>
<tr>
<th>For neutral soap</th>
<th>For superfatted soap</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lard............</td>
<td>100 100</td>
</tr>
<tr>
<td>Potassium hydrate used........</td>
<td>22·8 20·98</td>
</tr>
<tr>
<td>“ required.........</td>
<td>19·6 18·62</td>
</tr>
<tr>
<td>“ excess........</td>
<td>2·7 2·36</td>
</tr>
</tbody>
</table>

This comparison shows that the quantity of alkali used was in both instances too large for producing even a neutral soap, and it accounts for the results obtained on applying the calomel test to the products, the excess of potash amounting to 13·7 and 7·0 per cent. of the quantity requisite for that purpose in the respective instances.

The reaction given by the soap prepared with the proportions of lard and caustic potash for obtaining superfatted soap, on applying the calomel test, was so very slight, although the soap contained 7 per cent. of potash in excess of neutrality, that the utility of this test appeared to be very doubtful. On applying the test to soap ascertained by analysis to contain excess of alkali, it was found that it failed to indicate the presence of any appreciable quantities of free alkali, which were immediately detected when the alcoholic solution of the soap was tested with phenol-phthalein. I do not think, therefore, that the calomel test can be relied upon as a satisfactory means of ascertaining the neutrality of soap.

In view of the probability that superfatted soap may become an article required by pharmacists, I would suggest that the method most suitable for the preparation of a superfatted soap is to regulate the proportions of fat and potassium hydrate used according to the degree of superfattening desired in the soap. For that purpose the saturating power of the fat should be determined as above, and the amount of potassium hydrate in the caustic potash determined. In the case of lard, 18·8 may be taken as a sufficiently close approximation to the saturating power of 100 parts, and the quantity of caustic potash, of known strength, requisite for producing either a neutral soap or one containing any desired percentage of the fat in an unsaponified state, can be ascertained by a simple calculation.

Thus, for instance, in the case above stated, when the caustic potash contained 81·7 per cent. of potassium hydrate, 100 parts of lard would require 23·99 parts of the caustic potash to produce a neutral soap, and if it were desired to leave 6 per cent. of the fat unsaponified, the quantity of such caustic potash to be used would be 22·79 parts. The advantage of this method of operating would be the greater certainty obtained as to the nature of the product.

Practical Pharmacognosy.

(Continued from p. 23.)

SYSTEMS OF TISSUE.

BARKS (concluded).

Cinchona Bark.

Though this bark does not display any great peculiarities in its minute structure, it has afforded work for numerous investigators, since Weddell first examined it about 1849. The cinchona barks of commerce show no trace of epidermis, this being replaced by a sorky layer of the usual tabular cells. In several species the formation of secondary cork also takes place, and the presence of the rhytiodina thus formed affords a useful means of distinguishing them. It is of constant occurrence in Cinchona calisaya, but not so common in *C. succirubra* and others. Where it occurs to any extent, the whole of the outer tissues are displaced, and the bark, as in the case of the old flat Calisaya, consists exclusively of phloem tissues. The middle bark of cinchona consists, as usual, of parenchyma, in which appear more or less numerous isolated stone-cells in some cases. Laticiferous ducts, consisting of large, soft, elongated, unbranched cells (Figs. 24, p. and 25, M), occur where the middle and inner barks unite. When stone-cells and ducts are absent, the probable cause is the formation of rhytiodina, resulting in the displacement of the tissues containing them. The inner bark consists of primary and secondary medul-

*Zeitschrift für Analytische Chemie,* xviii., 199-203.

Vol. LV. (Third Series, Vol. XXV.), No.
lary rays alternating with rays of phloem, the bast fibres in the latter being short, obtusely-pointed, and frequently isolated. The walls of these fibres are strongly thickened by secondary deposits, and show a distinct stratification. When softened by caustic soda, concentrated sulphuric acid, or ammoniacal oxide of copper, the walls where thickened assume a spiral appearance. When not irregularly scattered these fibres form radial rows transversely intersected by narrow strips of parenchyma, or they are closely packed in short bundles. These contain from three to seven fibres only, whereas in many other barks analogous bundles consist of a large number of fibres. To this distinction is due the difference in fracture in barks, those with long bundles having a fibrous fracture, whereas cinchonas exhibit a short one. The parenchymatous cells of the bark are loaded with small starch granules, and, in several cinchona barks, numerous cells of the medullary rays and middle bark contain resin or crystals of calcium oxalate.

These cells have thickened walls, and the crystal cells frequently appear indented into the bast cells, as in quebracho bark. Other cells contain aggregations of minute pulverulent crystals.

The methods used in cultivation result in modification of the structure of cinchona bark to some extent, and barks from which the cortex has not been removed are now much more common than formerly.

In red cinchona bark (Fig. 24) stone-cells are absent, and the large laticiferous ducts (p) are often filled with cells, whilst the bast fibres are in interrupted lines. The tangential section through the primary bark (S, Fig. 25) shows two of the laticiferous ducts (Ml), one collapsed, and a cell (kr) in the parenchyma containing pulverulent crystals (kristalsand) of calcium oxalate. A similar section through the secondary bark of C. ledgeriana (L, Fig. 25) shows two such cells (kr) in the medullary ray (crst), together with two thick-walled bast cells (b), bast parenchyma (p), and sieve tubes (a) with plates. The narrow cavities and thickened walls of the short bast fibres are clearly shown in Fig. 26.

Calisaya bark much resembles the red bark in structure, the young bark containing a layer of primary cork, no stone-cells, and a number of large, laticiferous ducts near the bast rays. In the flat bark, however, as p 20.—Short bast fibres from Ch—already stated, bast of one bark. x abt. 20. (Plücker). tissue only is found, the fibres being arranged singly or in pairs and in radial rows. Bands of secondary cork are also of frequent occurrence. A well illustrated and detailed description of the minute structure of various cinchona barks will be found in Part II. of Tschirch and Oesterle's 'Anatomischer Atlas der Pharmakognosie.'
it was contended that whether the foregoing propositions be tenable or not, the article containing mor-
phine was sold in such a way that the retailers could
know nothing of its contents; the precautions pre-
scribed; by the Pharmacy Act could therefore not
be applied to such a sale; and, consequently, these
circumstances sufficiently justified the sale of such
articles by persons ignorant of the presence of poison
in them, and of the evil consequences it might
produce.

There is nothing novel in these propositions, and
though for a time their superficial plausibility
“impressed” the judges in previous cases, they
utterly failed to have a similar influence upon the
Master of the Rolls and the Lords Justices sitting
with him in the Court of Appeal. On the con-
trary, their minds were throughout directed to the
question “What is the meaning of the Pharmacy
Act?” and the only conclusion they could come to
was that its object is to confine the sale of poisons
to the hands of legally authorised persons—to pre-
vent grocers and other unqualified persons from
selling articles containing poison, whether they
know that to be the fact or not. Everyone of the
propositions above stated was emphatically nega-
tive by the Master of the Rolls and the Lords
Justices, and the appeal from the decision of
Justices Charles and Bruce (iii., p. 907) was dis-
missed without a shadow of reservation.

In this case the appellants had not only the
advantage of the keen persistency of Mr. Bossey,
but also the assistance of a more eminent counsel
in the person of Mr. Fletcher Moulton, Q.C., M.P.
The result was a considerable prolongation of the
case; but as in other applications of great guns,
there was the attendant risk that the energy
developed might operate in the wrong direction.
The heavy ordnance of the Bar is often useful for
giving effect to sophistical arguments; but when a
case turns upon hard facts, a thorough acquaintance
with them is indispensable, and the most charitable
view to take of Mr. Moulton’s part in this case is
that he was wanting in that essential equipment.

As regards the construction and future adminis-
tration of the Pharmacy Act, a very great advance
has been made by the hearing of this appeal. As
evidence of that it may be mentioned that the
Grocer, which has hitherto generally maintained
a discreet silence on the subject, now endeavours
to show that the judges were impressed with Mr.
Moulton’s assertion that “the endeavour to secure
a monopoly” was the main object of the Pharma-
cutical Society. Our readers will be able to judge
from the report how far there is any ground for that
statement (see report, pages 54 and 55). Our con-
temporary also clings to the belief that the ques-
tion—What is a poison?—must be determined by
the quantity of the thing to which the term poison
is applicable. There may be some temporary com-
in that belief; but, in our opinion, it is the only foundation for the Grocer's plaintive expression of regret that "the present doubtful state of the law is most unsatisfactory and perplexing."

At the same time, the fact remains that, though recent interpretations of the Act render its actual bearing much clearer, difficulties arise from time to time with regard to its administration. The latest instance of this occurred in a case heard at St. Helens on Wednesday, of which a brief interim report is given at page 67. A detailed report will be published in next week's Journal, and it will then be seen how the conflicting nature of the evidence resulted in the adverse decision of the judge.

SOCIETY OF CHEMICAL INDUSTRY.

The proceedings of the annual meeting of this Society commenced on Wednesday, in Edinburgh, with a general session in the Queen Street Hall. There was a large gathering of members, and the President was supported on the platform by Baillie DUNLOP, Dr. JOHN MURRAY, Professor CRUM BROWN, Dr. STEVENSON MACADAM, and others. In the absence of the Lord Provost, who is now at Windsor to receive the honour of knighthood, Baillie DUNLOP welcomed the Society to Edinburgh.

After the opening ceremonies of welcome by the civic authorities and their acknowledgment by the President, the report of the Council was read, showing a steady increase in the number of members, notwithstanding some fluctuation by reason of deaths. At the last annual meeting the Society had 2784 members; it has now 2826. There has been a considerable increase in the number of papers contributed to the Society's Journal, indicative of greater activity. The excess of income over expenditure has, however, been rather less than in the previous year, although the financial position is generally satisfactory.

Among other matters referred to in the report, the desirability of amendment in the law relating to patents was mentioned as having engaged the attention of a committee, with the result that it has been decided to take action in this matter at the earliest moment that the general course of public business will permit, with a view to obtaining a Royal Commission to consider the whole subject. The proposed alterations of the Society's bye-laws, which the Council has decided to submit for acceptance, were described, and the advantages likely to result from them pointed out. Another circumstance of great interest in connection with the work of last year is the establishment of a section of the Society in New York. This is a very important advance, and it is to be regarded as the first step towards an international organisation for promoting improvements in the industrial arts by applications of chemical science, which may lead to great results.

The President, in his address, made special reference to the utility of the Society in promoting scientific knowledge and its application to industrial arts, pointing out the signal deficiencies of our own country in that respect as compared with others. He especially insisted upon the desirability of research as being a national necessity in this respect, but it is a striking illustration of the benighted state of mind from which we are only beginning to emerge that he should have associated the word research with the emasculating adjective "original." But that mistake was largely compensated for by the remarks showing the practical gain to the nation and to industry generally, resulting from investigations such as those of WELDON and PERKIN, the one having contributed to the cheapening of every yard of calico and every quire of paper, while the other originated an industry which has revolutionised the arts of dyeing and calico printing. Such services are too little appreciated by British manufacturers, and the means by which they are to be facilitated for their own and the national benefit are still almost ignored. In connection with this subject, the insufficiency of our educational system and of the existing law of patents was mentioned as urgently requiring amendment. The vast field of inquiry opened up by the discovery that—in some of the most important manufacturing industries, and even in familiar domestic operations—minute organisms, whose existence was unsuspected a few years ago, are really the effective factors which determine results, was added as a case in point. On that basis and from the point of view of other recent discoveries, a prophetic sketch of the possible future of industrial arts was briefly sketched upon the lines suggested by BERTHELOT, and the very interesting address was concluded by a description of seaweed products not altogether in harmony with its general tenour.

The conversations in the evening at the Museum of Science and Art, which was carried out with great success, was very largely attended, affording agreeable opportunity for social intercourse and the formation of acquaintances. In other respects, also, the Edinburgh meeting promises to be one of the most useful, interesting, and successful among the annual gatherings of the Society of Chemical Industry.

URINE TESTING.

In the reprinting of Sir GEORGE JOHNSON's paper on the testing of urine in last week's Journal the possibility of mistaking the abbreviations for the grammé and the gram was unfortunately illustrated; the composer having, with perverse ingenuity, put "grammé" for "gr." throughout the paper. To remedy this mistake two pages of the Journal (26 and 26) have been reprinted for the purpose of being substituted for those in which the errors occur, and are issued with the present number.

JOULE STUDENTSHIP.

MR. J. D. CHORLTON, B.Sc., of Owen's College, Manchester, has been elected to the first Joule Studentship by the President and Council of the Royal Society, upon the recommendation of the Committee entrusted with the duty of making the award.

AMERICAN PHARMACY FAIR.

According to the New England Druggist it is intended to hold a "medical and general pharmacy exhibition of the most comprehensive character in Mechanics' Hall, Boston," early next year. It will be known as "The American Pharmacy Fair," and is intended "to include on a large scale—absolutely every article and product in the daily trade of an up-to-date retail druggist."

EXAMINATIONS IN LONDON.

July, 1894.

Present:—Mr. Carteighe, President; Mr. Cross, Vice-President; and all the members of the Board.

MAJOR EXAMINATION.

Forty-seven candidates were examined. Twenty-one failed. The undermentioned twenty-six passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Anstee, Edward Percival ... Bedford.
Ashby, Charles Edmund ... Weston-super-Mare.
Athey, George Hedley ... Morpeth.
Batler, Ernest Charles ... Stamford Hill.
Cowl, William Stephen ... Union Mills.
Cox, Harry Bertrand ... Skepton Mallet.
Davies, Robert Fisher ... Pontardawe.
Dyson, Herbert ... Derby.
Foden, Thomas Henry ... Birmingham.
Gupta, Frederic Waalde ... Lyne.
Gullett, Albert Ambrose ... London.
Greig, John ... Montrose.
Harvey, Thos. Featherstone ... Slieby.
Hayward, Walter Edwin ... Padiay.
Henry, Thomas Anderson ... Barrow-In-Furness.
Hill, Aubrey Thomas ... Boston.
Jackson, Thomas ... Preston.
Lander, Arthur ... St. Kylene.
Martin, George Hymers ... Gateshead.
Maskell, William ... Easingwold.
Mercer, Frank Norland ... Farnworth.
Roberts, George Daniel ... Spalding.
St. Cyné Etienne Lamine ... London.
Southall, Horace ... Birmingham.
Ward, Joseph William ... Gloucester.
Williams, William ... Carnarvon.

EXAMINATIONS IN EDINBURGH.

MAJOR EXAMINATION.

Three candidates were examined. One failed. The following two passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Highfield, Henry ... Sheffield.
Turner, John William James ... Sheffield.

Provincial Transactions.

THREE TOWNS AND DISTRICT CHEMISTS' ASSOCIATION.

The quarterly meeting of this Association was held at the Foresters' Hall, Plymouth, on Wednesday, July 11, at 3 p.m., Mr. J. O. Netting, President, in the chair. Four new members were elected and one honorary member (Mr. F. M. Holmes). A unanimous vote of thanks was passed to the Pharmaceutical Society for their liberal gift of a matura media cabinet. A resolution was passed supporting the draft Pharmacy Acts Amendment Bill, and it was decided to have a dinner in October. The following paper was then read:—

PHARMACY AS PRACTISED IN FRANCE.

BY C. J. PARK, M.P.S.

There are two grades of pharmacists recognised in France as in England. The pharmacist of the 1st class is put in charge of a pharmacy in any part of France, whilst the pharmacist of the 2nd class is restricted to a certain degree in this respect.

Elèves, or assistants, are required to have passed certain standards at the lycées, or schools, before they could be registered as "élèves en pharmacie" and commence their studies at one of the schools of pharmacy.

All these schools, situated in different parts of France and generally associated with schools of medicine, with the exception of one at Lille, are under the control of the State, which appoints the professors, fixes the fees, etc. Some only of these schools have the power of granting diplomas of the title class. Students have to be twenty-five years of age before presenting themselves for examination, and are required to have been six years engaged in pharmacy, and to have followed the course at one of the schools for three years. The subjects taught at the schools are natural history, botany, physics, theoretical and practical chemistry, and toxicology.

French chemists are only allowed to have one shop each, and are not allowed to work in conjunction with unqualified persons. It is illegal for a medical man in conjunction with a pharmacien to give gratuitous advice and reap a benefit from the prescriptions.

Pharmacists have the sole right of compounding and retailing medicines for human beings, either for internal or external use. Medical men situated in rural districts where there is no chemist are allowed to dispense medicines, but if they visit a patient who lives near an established chemist, they are not entitled to send medicines. Hospitals and religious communities can compound medicines for their inmates.

Secret medicines are strictly illegal, and the formulars of all specialties have to be submitted to a board appointed by the State and approved of before being allowed to be placed before the public.

French pharmacists open generally at 7 a.m., and close at 10 p.m. all the year round, Sundays included, and someone is supposed to be present at all hours for cases of necessity. Their sales are confined strictly to drugs, chemicals, and mineral waters, and it would be considered unprofessional to handle the variety of toilet articles, etc., which is often an important part of the business of their English colleagues.

The social status of the French pharmacist is higher than in England, and if serving in the Army, he ranks as a commissioned officer the same as a surgeon.

The chief poisonous drugs and chemicals are required by law to be kept in a locked cupboard in the pharmacy, and the pharmacies are visited at least once a year by officers appointed, who examine scales, poison cupboard, register of poisons sold, prescription-book, and stock; they can confiscate anything faulty if found, and the owner is fined in that case.

The Codex, or pharmacopoeia, is hardly up to the level of modern pharmacy, and many substances which are of use to the chemist will be eliminated. The compilers of this work, like those of our own pharmacopoeia, are evidently very conservative.

Prescriptions are written in the mother tongue, and the weights and measures used are according to the metric system. All substances are weighed; not an unmixed advantage, considering the different specific gravities of the substances employed.

Wines and syrups are largely used as vehicles in dispensing; cachets are largely used; suppositories are generally about thirty grains, of a conical shape, resembling an ordinary wooden vent plug. Doseometric grannies, resembling homeopathic phials, are largely prescribed; these are generally used when prescribing patent medicines such as strychnine, digitalis, arsenic, etc. Small gelatin capsules, termed "perles," containing either, chloroform, turpentine, creosote, salol, etc., are in frequent use. Liniments are largely prescribed, and alcohol being low, they can be used freely without entailing a large expense to the patient. "Bains," or preparations for medical baths, are in general demand; also ointments known technically as "pommades."

After the usual vote of thanks, the meeting terminated.
Parliamentary and Law Proceedings.

PROCEEDINGS UNDER THE PHARMACY ACTS.

APPEAL BY DEFENDANT IN THE CASE OF THE PHARMACEUTICAL SOCIETY v. ARMSON.

Powell's Balsam of AnisFuck.

This case came on for argument at the Court of Appeal on Thursday, July 12, before the Master of the Rolls, Lord Justice Kay, and Lord Justice A. L. Smith, Mr. Fletcher Moulton, Q.C., M.P., and Mr. Bosley, for the appellant; Mr. Crump, Q.C., and Mr. T. R. Grey for the respondents.

When the appeal was called on, Mr. Bosley said he appeared with Mr. Moulton, who was at that moment cross-examining a witness in another court, and he asked that the case might be deferred for a short time, but the Master of the Rolls said he had better proceed.

Mr. Bosley: This is an appeal, my Lords, from the Divisional Court affirming the judgment of the County Court in an action brought to recover a penalty under the Pharmacy Act, 1868.

Lord Justice Kay: May I ask, if you have leave to appeal?

Mr. Bosley: Yes, my Lord. The action is brought by the Pharmaceutical Society against the appellant, Armson, for selling a poison, he not being a qualified chemist and druggist, and the question really is whether a proprietary medicine known as Powell's balsam of aniseed is a poison within the meaning of the Pharmacy Act, and therefore can only be sold by properly qualified chemists and druggists.

Lord Justice Smith: What is it used for, Mr. Bosley?

Mr. Bosley: It is for coughs and colds, my Lord, a remedy often prescribed.

Lord Justice Smith: Is it taken internally or rubbed on externally?

Mr. Bosley: It is taken internally, my Lord.

The Pharmacy Act is the 31 and 32 Vict. cap. 121.

The Master of the Rolls: What section, please?

Mr. Bosley: The action is brought under section 15. "From and after the 31st December, 1868, any person who shall sell or keep an open shop for the retailing, dispensing, or compounding poisons, ... not being a duly authorised pharmaceutical chemist ... shall for every such offence be liable to pay a penalty or sum of £5, and the same may be sued for, recovered, and dealt with in the manner provided by the Pharmacy Act," that is the former Act, under which the penalties are recovered by action in the County Court.

The Master of the Rolls: This was an appeal from the County Court.

Mr. Bosley: Yes, my Lord.

The Master of the Rolls: The County Court judge held it was a poison. That is a fact, is it not? How do you get over that?

Mr. Bosley: I submit it is not really a question of fact.

The Master of the Rolls: Is it not? I only ask you. You know, it strikes me you have a difficulty there to start with.

Mr. Bosley: The difficulty is to define really what is a poison under the Act.

Lord Justice Kay: That is a fact surely; whether it is a poison or not is a fact.

Mr. Bosley: I submit that is really a question of law.

The Master of the Rolls: A question of fact! Lawyers know a great deal, but I do not know that they know whether a thing is a poison or not unless they take it, and if they did there would be an end of them.

Lord Justice Kay: I suppose there was medical evidence on this subject?

Mr. Bosley: Yes, my Lord.

Lord Justice Kay: On that evidence the judge had to decide.

Mr. Bosley: It arose in this way, my Lord. By the Act there are certain articles specified in a schedule to the Act which are to be deemed poisons within the meaning of the Act. Then the question is whether, if a very small quantity of one of those articles be sold—

The Master of the Rolls: Have you got the facts found by the County Court judge?

Mr. Bosley: I have the judgment of the County Court judge.

The Master of the Rolls: We ought to have it.

Mr. Bosley: The question is whether the Act applies.

Lord Justice Smith: You said something about schedule A. In what section is schedule A referred to in the Act?

Mr. Bosley: In section 17.

Mr. Crump: And section 2: "The several articles named or described in schedule A shall be deemed to be poisons within the meaning of the Act."

The Master of the Rolls: Where is that?

Mr. Bosley: That is section 2, my Lord.

The Master of the Rolls: The Pharmaceutical Society has power to add to that schedule, its additions being sanctioned by order of the Privy Council. It does add to it from time to time. That schedule consists of two parts, and the poisons in the first part and in the second part are dealt with differently in the Act with regard to the restrictions upon their sale. Poisons in the first part of the schedule can only be sold (even by a chemist) to a person whom he knows, or to some person who is introduced by a person whom he knows, and he has to enter the particulars in a book.

Lord Justice Smith: What section is that?

Mr. Bosley: Section 17. Then with regard to those in part 2 they have to be labelled "poison."

The Master of the Rolls: Has this been dealt with? You call it by some name, but the judge calls it morphine.

Mr. Bosley: In this cocoa bottle of Powell's balsam of aniseed, which consists of six or eight different drugs, there is one-tenth of a grain of morphine. The Master of the Rolls: I only wanted to ask you whether the Society has said that morphine is a poison, and whether the Privy Council has adopted that judgment.

Mr. Bosley: It is one of the poisons scheduled in part 2.

Lord Justice Kay: Opium and all preparations of opium or poppies are scheduled in part 2.

Mr. Bosley: Yes.

Lord Justice Kay: Now tell me how part 2 is to be sold. Which section is it?

Mr. Bosley: Section 17 deals with it, my Lord—the restrictions.

Lord Justice Kay: "It shall be unlawful to sell any poison unless the box, etc., is labelled," and so on.

Mr. Bosley: Then with regard to articles in part 1, they are only to be sold to a person known to the chemist or introduced to him. If the article is in the second part of the schedule, then it is labelled "poison."

Lord Justice Smith: Whereabouts is that?

Mr. Bosley: At the beginning of the section it says: "It shall be unlawful to sell any poison, either by wholesale or retail, unless the box, bottle, vessel, wrapper, or cover in which such poison is contained be distinctly labelled with the name of the article and the word 'poison,' and with the name and
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS

July 11, 1894.

address of the seller of the poison." Then it goes on to say that it shall be unlawful to sell any poison in the first part of the schedule to any person unknown to the seller.

Lord Justice Kay: First of all, none of these things in schedule A can be sold except by a proper chemist.

Mr. Bonsey: No, my Lord; they cannot be sold except by a chemist.

The Master of the Rolls: This was a grocer.

Mr. Bonsey: That is to say, they cannot be sold in their simple state.

Lord Justice Kay: The simple state. This says, "Opium must be pure morphine."

Mr. Bonsey: What I mean is this. If I were to go into a shop and ask for morphine or opium, I can only get that from a chemist.

Lord Justice Kay: Did not the County Court judge find that this was a preparation of opium?

Mr. Bonsey: No; not that Powell's balsam of aniseed is a preparation of opium—it is a compound.

Lord Justice Kay: "The bottle was found to contain among other ingredients one-tenth of a grain of morphine, which is the chief medicinal principle of opium, and in its pure state a dangerous poison. It was not disputed that morphine was a poison when the Act was passed."

Mr. Bonsey: All that the County Court judge has found is, and of course it was not disputed, that one of the ingredients of this Powell's balsam of aniseed—is, to the extent of one-tenth of a grain—was morphine, one of the poisons scheduled in the Act. Then the only evidence with regard to the effect of that is this—

The Master of the Rolls: Suppose a grocer puts more than one-tenth of a grain by mistake, where would he be?

Mr. Bonsey: The grocer does not dispense it, my Lord. He merely sells it by retail.

The Master of the Rolls: Who makes it?

Mr. Bonsey: The manufacturers—Messrs. Powell.

The Master of the Rolls: The grocer sells it. But suppose the manufacturer or his man makes a blunder?

Mr. Bonsey: Well, my Lord, the grocer does not know anything about it.

The Master of the Rolls: Then the question is whether he ought to sell it if he does not know.

Mr. Bonsey: No one knows. All these proprietary medicines, your Lordship knows (what are called proprietary medicines, on which a government duty is levied), are simply preparations. They are called specific remedies, and neither the chemist nor the grocer knows as a matter of fact what they do contain; therefore the chemist would be liable to a penalty under the Act if he sold one of these proprietary medicines without entering in a book the contents, that is, the ingredients, if it happened to contain a poison in part I of the schedule. It so happens in this particular case that it is in part 2.

Lord Justice Kay: I see what the learned judge has decided. He says, "If the whole of this bottle were taken by an infant it would kill him."

Mr. Bonsey: If the whole thing were taken all once.

Lord Justice Kay: Therefore, it is a poison. That was decided, in the case which he referred to recently, that if the whole of the contents of the bottle were a poison then it comes within the Act.

Mr. Bonsey: Then it is the difficulty. Does it depend on the size of the bottle?

Lord Justice Kay: It is one of the preparations mentioned in the schedule.

Mr. Bonsey: Does it depend upon the size of the bottle in which this medicine happened to be sold whether it is a poison? The judge has found that the only evidence was that if a child happened to take the whole bottle at once it might be injurious, and that if an infant took it all at once it would probably be fatal. That was the strongest way in which it could be put by the witness, Dr. Luff, who was called for the plaintiff. The evidence before the County Court judge with regard to that was simply that of Dr. Luff. He said if the whole bottle were taken at once by a child in ordinary health it would certainly be injurious, and might be fatal, and to an infant it very probably would be fatal; that is to say, assuming the child took the whole bottle at once. Will the question as to whether a thing is a poison or not depend merely upon the size of the bottle in which it is sold?

Lord Justice Kay: The first question is whether it is a preparation of opium? If it is a preparation of opium you are distinctly violating the Act of Parliament in selling it. Then, if it is necessary to go further, the second question is whether, as sold by you, it is not possibly dangerous?

Mr. Bonsey: The question, my Lord, has been considered—the same point—in two cases in the Divisional Court.

The Master of the Rolls: Are we not bound thus far? I do not know what your law is, but by the facts he says: "If it is a preparation of opium, given on behalf of the plaintiff, that if the whole of the contents of the bottle were taken at once by a child in ordinary health, it would certainly be injurious, and might be fatal, and to an infant very probably fatal." This evidence was not contradicted or seriously impugned. He found that as a fact. I do not say what your law is, but he finds that as a fact, and we must take that to be the truth.

Mr. Bonsey: Yes, my Lord. I say that would apply to innumerable things which are perfectly harmless and beneficial.

Lord Justice Kay: But then they would not be opium or preparations of opium. You are dealing with one of the things prohibited in the schedule. Take this case for example. Suppose it was a preparation of opium, the quantity of which would not harm a child if he drank the whole of it, but this thing stands prohibited by this schedule. Was it not decided in the case to which the learned judge referred that mixing it with other ingredients does not make it any the less a preparation of opium?

Mr. Bonsey: The case to which the learned judge refers, which is the Pharmaceutical Society v. Piper.

Lord Justice Kay: That was chlorodyne.

Mr. Bonsey: Yes, my Lord. It was argued there that the Act does not apply where only one of the ingredients in the compound is one of the scheduled poisons in the Act.

The Master of the Rolls: Where is that case?

Mr. Bonsey: The Law Reports for 1893, 1 Q.B.D., page 886. What was decided there was that it does apply even if it is only one of the ingredients of a compound, and the judges held that the thing in its entirety, that is to say, if the whole bottle had been taken at once, was a poison; although, so far, the learned judges expressed themselves, I think, that they had great doubt whether that was the proper interpretation of the Act. In that case, my Lord, it was chlorodyne, and there was a very much larger quantity of morphine there. Then Mr. Justice Collins says in his judgment, "I am not by any means sure that I have arrived at the right conclusion in the matter . . . . . . . I think in this particular case it is clear that the evidence, viz., chlorodyne, does come within the designation 'poison' within the meaning of the Act in question . . . . . . It is also found that in the bottle sold there was sufficient morphine to kill an adult if the whole contents of the bottle were taken at once. Therefore, i
the particular case before us, I think we may take it that the thing sold was, in its entirety, a poisonous thing, that is to say, that a small quantity of it would kill." I am also of opinion that it is a compound into which poison enters as one of the ingredients, and that, on that ground, it is within the purview of the Act, and comes under the designation of 'poison,' and is dealt with by the Act. But while I am of that opinion as to this particular matter, viz., chlorodyne, I do not think it is necessary to lay down any rule which would cover every possible case where some infinitesimally small amount of poison enters into a larger compound." Then there was also another question raised in the case, whether it was a patent medicine, and therefore exempted.

Lord Justice Kay: I understand you to say your bottle is labelled so as to show it is intended to be used by infants.

Mr. Bonsay: Yes, there are certain prescribed doses.

Lord Justice Kay: It is intended to be used by infants, and if the whole were given to an infant, that infant might be poisoned.

Mr. Bonsay: I think the smallest dose prescribed on the bottle is for a child of four years of age.

The Master of the Rolls: I see you argued that case?

Mr. Bonsay: Yes, my Lord.

The Master of the Rolls: What is the difference between that case and this? Is there any there?

Mr. Bonsay: There is another case to which I am going to refer.

The Master of the Rolls: You have a right to say this case is wrong, of course.

Mr. Bonsay: Certainly, my Lord.

The Master of the Rolls: I ask you whether this appeal does not involve the question whether that case is right or wrong?

Mr. Bonsay: It does, my Lord, but the court gave us leave to appeal in this case.

The Master of the Rolls: For the purpose of considering Piper's case?

Mr. Bonsay: Yes, my Lord. They said they were bound by Piper's case.

The Master of the Rolls: That is quite true.

Mr. Bonsay: I submit that Piper's case is really wrong on that point.

The Master of the Rolls: I understand. That is quite legitimate. You have a right to raise that point here.

Lord Justice Kay: Is not the mischief, which this Act was intended to prevent, the dealing by people who are not chemists with medicines to be taken internally, which either are preparations of opium or contain preparations of opium sufficient, if the whole be taken, to kill?

The Master of the Rolls: I only want to get the question we have to decide, that is all. I do not think we need trouble in this case whether the article sold, that is, the preparation or compound, or whatever you call it, had so little poison in it that it could not kill any human being, or injure them. We have not got to decide that, because here you have a finding that it will injure a child and perhaps kill, and if it were an infant it would probably kill him.

Mr. Bonsay: Yes, my Lord. Then, my Lord, that is a wide definition of the word "poison," because if it depends merely on the quantity taken——

The Master of the Rolls: I was only saying (I do not decide against you at present), that I do not think it is necessary to decide whether, if the compound were which could not hurt any human being at all, it would be within the Act.

Mr. Bonsay: Then, my Lord, if this judgment in Piper's case is right, and that, under the Act, it be sufficient to show that one of the ingredients of a medicine is one of the scheduled poisons, then it is no matter what the quantity is.

The Master of the Rolls: If you like to argue that point, I do not mind deciding it.

Mr. Bonsay: If that is sufficient, it does not matter at all whether taking the whole bottle is poisonous or not.

The Master of the Rolls: It may be that the thing will harm nobody, but that depends on who makes the compound; and the person who makes the compound really ought to be a skilled person, who knows how much poison will injure or kill a man or a child. That is what the Act means. Then if the Act means that, it goes further, in order to save the public, and says: If you choose to sell a thing without knowing what is in it, or knowing what is in it—it does not signify—in selling it you run the risk of its containing any poison, and if it contains any of the named poisons you are liable to the penalty.

Mr. Bonsay: If that was the intention of the Act it would have been extremely easy to say, in so many words, that it applies to a compound of which one of the ingredients is a poison within the schedule; and it does not say that, anywhere.

The Master of the Rolls: It need not say so. If it says: If you sell an article in which there is any, they need not say a compound.

Mr. Bonsay: It does not say that: All the Act says is that you shall not sell poison.

The Master of the Rolls: Your argument, it seems to me, must go this far. You might sell pure opium if you sold it under another name, if you called it—I do not know what you might call it—if you called it "body." 

Mr. Bonsay: It would be opium still; but if you have a chemical compound, say, of six or eight different drugs, and there happens to be, as there is in almost every medicine, a very small quantity of a poisonous drug, that is to say a drug which taken in a large quantity would kill, is that compound or medicine a poison within the meaning of the Act—that is to say, one of the scheduled poisons under the Pharmacy Act?

The Master of the Rolls: You say the penalty depend upon how much poison there is in it, and on a jury finding whether that quantity of poison would be such.

Mr. Bonsay: My first point is that the Act does not apply to a compound of which one of the ingredients is a poison scheduled in the Act.

The Master of the Rolls: Then you know, if there are two things in the compound, and half of it is one of those poisons, your argument says, very well, they may sell.

Mr. Bonsay: Because it is quite possible to have a combination of two substances producing a different one altogether.

The Master of the Rolls: It is, and it is quite possible the compound might kill anybody who took it.

Mr. Bonsay: Or it might not. You may have a chemical combination.

The Master of the Rolls: Supposing it was proved to the satisfaction of the court—I am only trying to test your argument—that whoever took a compound consisting of two things must be poisoned, you say there would be no penalty, because he did not sell the deleterious thing—the poisonous thing—by itself.

Mr. Bonsay: I do say so, my Lord. It may be that it would be wise to have legislation to cover that—but I say this Act does not cover that, and it was not intended by this Act. It may be an omission on the part of the Legislature.

Lord Justice Kay: See how far that goes. They are not to sell any preparation of opium unless they are qualified persons. Suppose opium and water or opium and any other thing you like were mixed in
certain proportion, would not that be a preparation of opium?

Mr. Bonsey: It might be if it were merely diluted with water.

Lord Justice Kay: Then the addition of something does not prevent it being a preparation of opium, nor does it cease to be a preparation of opium by the addition of other things?

Mr. Bonsey: That is one point in the case, my Lord. I submit there is a distinction between a preparation of a drug—what is commonly called a preparation of opium—and a chemical compound of which one of the ingredients happens to be a preparation of opium.

That is what I mean.

Lord Justice Kay: Still, if you sell the compound you sell the preparation of opium, which is an ingredient of it?

Mr. Bonsey: But it does not make the compound a preparation of opium.

Lord Justice Kay: Still, if it contains a preparation of opium you sell the preparation of opium.

Mr. Bonsey: If I only sell it in a combination of which it forms a part.

Lord Justice Kay: Take pure morphine, and mix it with sugar; you say they may sell that?

Mr. Bonsey: I should doubt whether they could.

The Master of the Rolls: Is not that a preparation of opium?

Mr. Bonsey: I am not quite chemist enough to answer that question.

Lord Justice Kay: It does not want a chemist to answer it.

Mr. Bonsey: I submit it does. It may be that sugar would not alter the effects of the opium at all.

The Master of the Rolls: When we were children the nurse used to give us grey powder, or some other nastiness with strawberry jam; you say they did not give us grey powder because they gave a compound of grey powder with strawberry jam.

Mr. Bonsey: I submit that compound and preparation are not the same.

The Master of the Rolls: Is the word compound used in the Act?

Mr. Bonsey: Yes, my Lord, in the schedule compound.

The Master of the Rolls: Which schedule?

Mr. Bonsey: One of the additions that were added by the Privy Council in 1869.

The Master of the Rolls: It is not in this Act then?

Mr. Bonsey: It is here, my Lord, on the left-hand page. [Handing copy of the poison schedule.] "Every compound containing any poison within the meaning of the Pharmacy Act, 1868, when prepared or sold for the destruction of vermin." Why should they there use the word "compound," if compound and preparation mean the same thing? All through, the schedule itself speaks of these different poisons and their preparations, which I submit is a chemical term.

The Master of the Rolls: I do not think this schedule does you much harm. It is "every compound containing any poison within the meaning of the Pharmacy Act, 1868, when prepared or sold for the destruction of vermin."

Mr. Bonsey: Yes, my Lord.

The Master of the Rolls: I hope you do not consider children vermin?

Mr. Bonsey: No, my Lord, what I mean is this. If preparation and compound mean the same thing—

The Master of the Rolls: I am saying that in your favour.

Mr. Bonsey: I claim that this is in my favour. I crave this in aid of my argument.

The Master of the Rolls: In saying that in your favour, I mean that addition is not against you in this case.

Mr. Bonsey: No, my Lord, I was going to point to it in aid of my argument.

Lord Justice Kay: You are using it because the word "compound" is used there. You want to construe the schedule of the Act as not including compounds because it is specially put in there.

Mr. Bonsey: Yes, my Lord, with great respect, I think I may say that in the court below, in Piper's case and in Delvoye's case, it was accepted also by the court that "compound" and "preparation" are not the same thing.

Lord Justice Kay: I do not believe there is any preparation which is not a compound.

Mr. Bonsey: It was never suggested that they were the same.

The Master of the Rolls: I do not say they are. I should say a compound was a preparation, but a preparation need not be a compound, if you ask me.

Mr. Bonsey: That may be so, my Lord; but when you talk of a preparation of a thing I submit that it means that the substance itself remains practically the same. Surely it could not be said that anything into which opium entered as an ingredient is a preparation of opium; surely that would be wrong as a chemical term—anthing into which it might happen to enter.

Lord Justice Kay: If you are right, the Act would be liable to evasion in the simplest way, for you would have nothing to do but put another ingredient with the opium, and then you could say it was not a preparation of opium, and it could be sold. Surely the Act cannot mean that.

Mr. Bonsey: I think, with great respect, the Act was simply intended to prevent the sale of poisons as poisons, as defined in the schedule to the Act. If it had not been so, if it had been intended to prohibit the sale of all medicines in which one of the ingredients happened to be poison, it would have been extremely easy to say so.

The Master of the Rolls: The people against you will say they have said so. You mean that they could have said so in words. What words?

Mr. Bonsey: Take, for instance, section 17.

Lord Justice Kay: You are in this difficulty—if you sell a compound, you sell everything which is included in the compound. If the compound includes opium, you sell opium.

Mr. Bonsey: You may sell it, or you may not sell it at all. If I may follow that out for a moment, as your Lordship knows, you may have a chemical combination of two substances, and the thing you produce is neither of those.

Lord Justice Kay: A chemical combination? You do not pretend that this is a chemical combination which alters the opium into something which is not opium.

Mr. Bonsey: But you might have.

Lord Justice Kay: I do not think you might.

The Master of the Rolls: What do you say to strychnine? Must it be simply strychnine?

Mr. Bonsey: I do not know whether that is in the schedule.

The Master of the Rolls: Yes, that is one. Medical men in our time give you something or other with strychnine in it as a tonic.

Mr. Bonsey: Yes, my Lord, it is a common tonic.

The Master of the Rolls: Do you say a grocer may go and make a compound of strychnine and sell it?

Mr. Bonsey: He cannot dispense it. A grocer cannot make up and prescribe. That is an entirely different thing.

The Master of the Rolls: Is it so? Would it make any difference if that grocer had made up this thing himself, and then sold it?

Mr. Bonsey: Yes, my Lord, because I submit that
one of the real objects of the Act was to deal with the question of dispensing.

Lord Justice Kay: It says retailing, dispensing, or compounding. Why do they except in section 17 the case of medical practitioners compounding medicines so as not to be within the Act? They may compound poisons and not be within the Act.

Mr. Bonsey: I am glad your Lordship refers to that. What I was going to say in a moment was this. Except for that provision in section 17, I say it would be clear that the Act did not apply to compounds, although one of the ingredients was a poison. It is only on that provision in section 17 that they can base their contention.

Lord Justice Kay: It says: "It shall be unlawful for person to sell or keep open shop. This is section 1—"—for, amongst other things, compounding poisons.

Mr. Bonsey: Yes, my Lord.

Lord Justice Kay: That must mean you cannot sell compounded poisons?

Mr. Bonsey: I may try to make myself clear. To answer to what the Lord Justice put to me, except for that provision in section 17, the Act would be perfectly clear. I submit that it only applies to the sale of poisons in what I may call their simple state: but it is by authority of that provision of section 17 that they say, therefore, you must infer that it does apply to a compound of which one of the ingredients is a poison. That is the argument on which they base their case.

Lord Justice Smith: Because they would not have made the exception.

Mr. Bonsey: Inferentially I say if that had been the object in the first part of section 17, it would have said: It shall be unlawful to sell any poison or any compound of which one of the Ingredients is a poison either by wholesale or retail. They want to read it in that way.

Lord Justice Smith: Suppose there was such a very small amount of poison that it would kill nobody, you would not say that was a poison, would you? But suppose so much was put in as to make the whole bottle poisonous, is it not within the Act then?

Mr. Bonsey: That arose in the case of the Pharmaceutical Society v. Delve, which is after Piper's case, in January of this year. There it was said that what is called "chloroform". That was a preparation of morphine. It was analysed, and the analyst said he found morphine, but did not estimate the actual quantity. He further said it was not a trace; it was more than a trace, but he was not instructed to take the quantity. It might be that the quantity was one-fifth of a grain per once, or three-fifths of a grain in the bottle: "I am not prepared to say whether taking the whole of the contents of the bottle would do an adult any harm." The Divisional Court there, Mr. Justice Charles and Mr. Justice Wright, held that that was not within the Act.

Lord Justice Smith: There was nothing to do harm.

Lord Justice Kay: Was it one of the articles in Schedule A?

Mr. Bonsey: Yes, my Lord, morphine. The same thing as here. That is making it depend really on the quantity. Merely whether the person or child taking the whole bottle at once would be injured. That is the only way you can reconcile those two decisions.

Lord Justice Kay: What puzzles me is that there is no provision in the Act as to the quantity of these articles in Schedule A.

Mr. Bonsey: No, my Lord, nothing about quantity.

Lord Justice Kay: You cannot deal with it at all, it does not matter what the quantity is.

Mr. Bonsey: But what I am trying to express is this, that as these two decisions stand, Piper's case and Delve's case, the court seems to have said that it merely depends on the quantity which happens to be in the bottle sold at the particular time. A person might go buy two or three bottles at once: but because he goes and buys a small bottle which only contains an infinitesimal portion, then that is not a poison; but if he goes and buys a large bottle it is.

The Master of the Rolls: If it is infinitesimal you may say it is not there at all.

Mr. Bonsey: But where, as in this case, the analyst says: "I found morphine; it was not a mere trace, it was more, but I did not actually estimate the quantity."

The Master of the Rolls: But the judgment is that it was infinitesimal.

Mr. Bonsey: I suppose I put it too high in putting it in this way, but it be the question if it is a substantial quantity, or is it the meaning of the Act that the question whether a thing is a poison or not depends upon the size of the bottle which happens to be sold of the particular compound.

The Master of the Rolls: That seems to me to go exactly that the Courts ought not to enter into any such question; but that if there are any of the prohibited things in it at all, a man must not sell it unless he be a duly qualified person.

Lord Justice Kay: A grocer could not sell the smallest possible amount of opium, although it would do nobody any harm, not even to the youngest infant. He has no right to sell any of it. Sections 1 and 2 absolutely prohibit him.

Mr. Bonsey: But the effect of that would be to prohibit him from selling proprietary medicines.

Lord Justice Kay: And a very good thing too.

Mr. Bonsey: It is not everybody who thinks so, my Lord. I mean they are useful medicines, especially to poor people who have not an opportunity of going to chemists and druggists.

The Master of the Rolls: Are you sure that those which are, as you say, useful to poor people, have any poisonous in them? Unless they have they may sell them as much as they like.

Lord Justice Kay: Is it not perfectly notorious that children have been killed in a very great number by taking these things containing poisons?

Mr. Bonsey: There was no evidence at all that any child was ever killed, taking Powell's balsam of aniseed. They were challenged with that at the trial, and no evidence was given of it.

The Master of the Rolls: I thought that most of the medicines you were speaking of had really nothing in them. They cure people, as I have been told by doctors, by reason of faith. A doctor once told me: "I cannot cure you unless you have faith in me;" on which I answered him that he would not cure me at all, for I had no faith in him.

Mr. Bonsey: Take such a thing as a cough lozenge.

Lord Justice Kay: There are plenty of ingredients for making quack medicines without taking those in the sour lot.

The Master of the Rolls: Do you mean to tell us that when we take cough lozenges we always take poison in them?

Mr. Bonsey: Nearly always, my Lord—you take morphine. I never will.

The Master of the Rolls: I will take no more, then.

Mr. Bonsey: As a matter of fact, in the British Pharmacopoeia there is a morphine cough looseng prescribed.
The Master of the Rolls: Do you mean to say that a grocer may sell that?
Mr. Bonsey: If Piper's case is right, he cannot. They are sold by grocers and hucksters all over the country.

The Master of the Rolls: If what you say about there is true, they had better not.
Mr. Bonsey: I am only saying it is convenient to poor people that they should have the opportunity of getting these things.

The Master of the Rolls: It may be for the convenience of poor people that they should be poisoned for nothing I know.
Mr. Bonsey: But they do not poison themselves with cough lozenges. Suppose if a man liked to take two or three boxes all at once he might make himself ill, or poison himself, but that applies to so many things.

The Master of the Rolls: I rather agree with you: but it seems to lead to the conclusion that we had better say that if they sell anything in which there is a poison we will inquire more about it.

Mr. Bonsey: May I point out this: that if that is the object of the Act, then section 17 is most inaccurately expressed, for this reason: If the object is that—then the proper thing is to say what it contains, then neither a chemist nor a grocer knows the contents of these things.

The Master of the Rolls: Stop a minute. Do not say neither a chemist nor a grocer, because a chemist—if he likes—can analyse the thing and find out.
Mr. Bonsey: Pardon me, my Lord. It is an extremely difficult thing if you produce to a chemist a bottle of stuff, and do not give him any indication of what is in it, to ascertain the actual composition. They have to analyse for almost every poison there is.

The Master of the Rolls: A chemist, I thought, could analyse a thing and find out for you directly what it contained.
Mr. Bonsey: As a matter of fact, one knows that if you go into a chemist's shop and ask for a bottle of Powell's balsam or a cough lozenge the chemist does not know what the ingredients are.

The Master of the Rolls: I do not agree with you at all. This is my belief: that he has in his laboratory tried the lozenges and found out what is in them.
Mr. Bonsey: These proprietary medicines are secret nostrums, and are so called in the Revenue Act. If a man sells what is called a secret nostrum as a remedy for a specific disease he has to pay duty. They are stamped with the government stamp. The chemist does not know anything more than the grocer what the contents of that bottle are.

The Master of the Rolls: I doubt it. I should think he did.
Lord Justice Smith: Why were patent medicines excepted? Why are they kept out?
Mr. Bonsey: I contended in Piper's case, and I still submit it is correct, that the word "patent" in that section includes proprietary medicines.

The Master of the Rolls: Which are not patented?
Mr. Bonsey: And so Mr. Justice Collins seemed to think for some time. For this reason: There are really scarcely any patent medicines in existence, but there are hundreds of proprietary medicines, and so there were at the time this Act was passed.

Lord Justice Smith: Are Holloway's pills a patent or proprietary medicine? There was an enormous compensation case about Holloway's pills in the Supreme Court, the costs over twenty thousand.
Mr. Bonsey: It was never patented, I am told, my Lord.

Lord Justice Smith: I mean the case when he was removed, for the building of these courts I think, and he had an enormous trade claim. I only wanted to know whether he was a patent medicine.

Mr. Bonsey: No, my Lord, neither are Cockle's pills. They are not patented. They are proprietary medicines.

Lord Justice Smith: But there are patent medicines, I suppose.

Mr. Bonsey: Extremely few. I think thirty, and only three of those contain poison. I think that was the evidence in Piper's case, and I forget how many hundreds of proprietary medicines.

Mr. Crump: The ingredients are all known in patent medicines.

Lord Justice Smith: I know. That is why I said.

Lord Justice Kay: You do not obtain a patent without some investigation.

The Master of the Rolls: If it is a new invention, could the Attorney-General refuse his fiat. I think he used to refuse in the old days, if the article to be patented contained a poison.

Mr. Crump: I believe so, my Lord.

Mr. Bonsey: I should think it is very doubtful whether you could patent a medicine at all in the strict sense of the term.

The Master of the Rolls: If somebody invents a new compound and it is patented, and somebody else sells that compound, of course it would be an infringement of the patent.

Mr. Bonsey: Let me illustrate it in this way. Suppose a doctor prescribed for a person who was dying, a patent medicine; would that be an infringement of the patent?

The Master of the Rolls: Doctors never do prescribe these patent medicines.

Mr. Bonsey: I contend that "patent" in section 16 really includes these proprietary medicines—that the word "patent" is a word meaning proprietary medicines. They are not called proprietary medicines by the ordinary public. The common term—for all those medicines which are sold with a stamp upon them—is patent medicines.

The Master of the Rolls: There is no such rule of interpretation.

Mr. Bonsey: Yes, my Lord, I want to point that out.

The Master of the Rolls: You are poisoning our minds with your compounds.

Mr. Bonsey: What I want to say with regard to section 17 is this: I want to make this point clear, if I can. In section 17 anybody who sells one of these poisons, or a compound containing a poison, if it is in part 1, even if he is a chemist, has to enter in a book the quantity of the article sold. Now Mr. Justice Collins in Piper's case said he could get out of that difficulty by construing the word "article" in one part of the section in a different way to "article" in the latter part of the section. When you speak of "article" in the first part of the section it means the poison itself, but when you speak of "article" in the latter part of the section it means the compound which is sold. He said that but for that interpretation, which I submit is an incorrect one, with every respect to the learned judge, that the chemist cannot possibly comply with the regulations of the Act, and submit that this impossibility shows that it was not the intention or the object of the Act to apply to proprietary medicines.

Lord Justice Smith: Why should not the man who made the medicine originally describe it outside the bottle, and put a small label on the bottom with the word "Poison"?

Mr. Bonsey: That is not sufficient; it is in part 1.

Lord Justice Kay: No, it can only be sold by a chemist.

Mr. Bonsey: And he has to enter the ingredients in a book with the date of the sale, the name and...
address of the purchaser, and the name and quantity of the article sold.
Lord Justice Kay: He must be a chemist and druggist within the meaning of this Act, and be registered under this Act, and sell in conformity with the regulations.
Mr. Bonsey: Yes; he has to enter the date of the sale, the name and address of the purchaser, the name and quantity of the article sold, the purpose for which it is wanted, and that entry must be attested by signature. Now, I say, the article sold means the poison, not the compound, because in the first part of the schedule it means the poison.
Lord Justice Smith: If you are selling under the first part of schedule A, you must be under the first part of section 17, must you not, as well?
Mr. Bonsey: Yes, my Lord.
Lord Justice Smith: First of all you must put on the bottle the name of the seller and the word "poison." Then, if you are in part 1 of schedule A, you are to go further.
Mr. Boonsey: Then you go through the formality of entering the quantity of the article sold.
Lord Justice Kay: This case in the first part of section 17 is not in schedule A.
Mr. Bonsey: I am using it as an argument to show that the Legislature could not have intended that it should have been applied to the sale of what everyone knows is a secret preparation, that is, a proprietary medicine, since no one, not even a chemist, could sell a proprietary medicine under those conditions, because he could not enter the quantity of the article sold.
Lord Justice Kay: There must be many proprietary medicines which do not contain any ingredients in this schedule. They are harmless enough, and can be sold by anybody; but if they contain ingredients in the schedule, why should not the Act apply to them?
Mr. Bonsey: It would prohibit their sale altogether.
Lord Justice Smith: I do not follow you, Mr. Bonsey. I am sorry to say. Why would it not do to enter in the book the name of the person who applies for it, what he wants it for, and the name of the article?
Mr. Bonsey: Because the article means the poison, not the compound.
Lord Justice Smith: Where do you find that?
Mr. Bonsey: If you will look further down the schedule.
Lord Justice Smith: Before you get to that word "article" it begins: "It shall be unlawful to sell any poison," and so on, "unless the box, bottle," etc., "be distinctly labelled with the name of the article, and the word "poison."
Mr. Bonsey: But this is where I get the argument. At the bottom of the section it says that "the provisions of this section shall not apply to any article when forming part of the ingredients of any medicine." Therefore, the word "article," in the lower part of the section, is clearly used as referring to the poison, and in section 2 it is used to the same effect.
Lord Justice Smith: How far is that down?
Mr. Bonsey: Near the end of the section. "Shall not apply to articles to be exported from Great Britain by wholesale dealers, nor to sales by wholesale to retail dealers in the ordinary course of wholesale dealing, nor shall the provisions of this section apply to any medicine supplied by a legally qualified apothecary to his patient, nor apply to any article when forming part of the ingredients of any medicine, etc."
The Master of the Rolls: "Dispensed by a person registered under this Act." You leave that out.
Mr. Bonsey: What I am pointing out there is, that there the word "article" means the poison, the ingredient; not the thing sold, not the bottle of medicine.
The Master of the Rolls: What do you get from that? If it is an article with two grains of strychnine in it, why is he not to put down two grains of strychnine? Here is schedule F, which says you are to put the date, the name and address of the purchaser, the name and quantity of the article sold, the purpose for which it is required, and the signature of the purchaser, or of the person introducing him.
Mr. Bonsey: He cannot do it, my Lord.
The Master of the Rolls: Why not?
Mr. Bonsey: Because he does not know.
The Master of the Rolls: Then he should not sell it.
Mr. Bonsey: That would prohibit the sale of proprietary medicines.
The Master of the Rolls: Except by properly qualified persons.
Mr. Bonsey: One knows that there is scarcely any antitoxin pill that does not contain poison of some kind.
The Master of the Rolls: You seem to know a great deal about medicine. I do not in the least doubt you do; but I have not any faith in you if you tell me that all antitoxin pills contain a quantity of poison. I do not believe that.
Mr. Bonsey: A very large number do, I am told.
The Master of the Rolls: That is another matter. I do not believe it. I have read some pre-scriptions given by great doctors for antitoxin pills, and I never saw any poison in their prescriptions.
Mr. Bonsey: Then all I say is that Mr. Justice Collins deals with Piper's case by saying that in the first part of the section the word "article" meant the bottle of stuff which was sold, but in the latter part of the section it meant the poison.
The Master of the Rolls: I am not sure he is not right. Why not?
Mr. Bonsey: Why should a different interpretation be put on the same word?
The Master of the Rolls: Because the context obliges you.
Mr. Bonsey: Why should you say that "article" all through the Act is used to designate the poison, and in a particular place calls the compound?
The Master of the Rolls: If the context obliges you to say so in a particular section, you have to say so.
Mr. Bonsey: My submission is that it is giving a strained construction to apply a different definition to the same word in the same section. Surely the whole Act was to apply to the sale of all proprietary medicines, of which one of the ingredients was a poison. It would have been very simple to have said so in the first part of the section.
The Master of the Rolls: To plain minds I cannot understand, if you were not to sell poison, how it can be said that you do not sell poison, if you sell a compound in which there is a poison. You sell poison. To plain mind that seems to me clear.
Mr. Bonsey: Because the Act itself only deals with poisons and their preparations.
The Master of the Rolls: That is begging the question, as it seems to me. The Act in the first or second section says you must not sell a poison.
Mr. Bonsey: Poisons are defined in the schedule to the Act.
The Master of the Rolls: Those articles which are mentioned in the schedule.
Mr. Bonsey: Those things and their preparations.
Mr. Bonsey: What I have said is that the first or second section comes to this: you must not sell the poisons named in the schedule. Then if you sell something with these poisons in them, you sell those poisons, to my mind.
Mr. Bonsey: My submission is that the Act says you shall not sell those poisons or preparations of those poisons. What the Pharmaceutical Society is doing here is endeavouring to give the meaning "pre-
paraphrase" to the word "compound," which is entirely different.

Mr. Bonsey: That a compound contains a preparation, but a preparation may not be a compound.

Lord Justice Kay: In this case: Suppose you mix together: all the articles in the first part of the schedule, according to your argument, you might sell them?

Mr. Bonsey: No, my Lord.

Lord Justice Kay: Why not? It would be a compound.

Mr. Bonsey: The whole compound would be a preparation of all the poisons.

Lord Justice Kay: You say a compound is not a preparation?

Mr. Bonsey: Then, my Lord, I put another extreme case. If you put one-tenth of a grain of one of these poisons with fifty other drugs, could you call the result a preparation of that first drug?

Lord Justice Kay: You would be selling one-tenth of a grain of that drug which you are prohibited from selling.

Mr. Bonsey: You are not selling the preparation of it.

Lord Justice Kay: Never mind the preparation; you are selling the one-tenth of a grain of that, and you are not allowed to sell the smallest fraction of it, because you are not a qualified chemist.

Mr. Bonsey: I do not know that I can say any more upon that point, my Lord. My submission is that such was not the object or intention of the Act.

Lord Justice Kay: The answer to you seems to me to be this: If your argument is right, it would be the easiest thing in the world for anybody to evade this Act. Indeed, I do not see how you could get over what I have just pointed out. If your argument about compounds be right, you could compound any two, three, or four of the poisons mentioned in the schedule, and then say you were not selling a preparation of any one of them.

Mr. Bonsey: I can only answer that by saying that compound and preparation are not really the same thing; obviously they cannot be.

Lord Justice Smith: Take chloroform, where you have no preparations added in the schedule. Suppose you sell chloroform—take a bottle half chloroform and half water—do you not sell chloroform?

Mr. Bonsey: That would be simply diluted. There are two of different strengths.

Lord Justice Smith: Suppose you take a medicine bottle and fill it up half with water and the other half with chloroform, do you not sell chloroform?

Mr. Bonsey: I think you would there.

Lord Justice Kay: Suppose you half filled the bottle with brandy?

Mr. Bonsey: There is brandy of different strengths also.

Lord Justice Kay: Would not that be selling chloroform?

Mr. Bonsey: I do not know that it would.

The Master of the Rolls: Can you say that it would not?

Lord Justice Kay: Supposing he were to put a few drops of chloroform into a bottle of brandy, I should not call that selling chloroform.

Lord Justice Smith: Then you come to de minimis.

The Master of the Rolls: What is that—a preparation of brandy?

Mr. Bonsey: I should call it brandy.

The Master of the Rolls: Very well. If it was brandy adit quasio.

Mr. Bonsey: That is my point as to the object of the Act. Of course, it may be that there was an omission in the Act; but what I say is that the object of the Act was never to include every proprietary medicine, or every medicine in which one of the ingredients was a poison. Then if it was, I say that in this particular case there was really no evidence that the article sold was a poison.

The Master of the Rolls: What do you mean by a poison? Is not a thing a poison which will poison somebody?

Mr. Bonsey: Does it then depend upon the quantity? Quantity surely cannot be an accurate definition of a poison. Apart from the Act altogether, when you talk of a thing which is a poison—suppose you poison yourself—anyone may poison himself with wine, or brandy, or many things.

The Master of the Rolls: No, I beg your pardon. Let us use words in their ordinary sense. Except in the views of—I do not know what you call them—the Temperance Society, a man does not poison himself with drinking beer; I suppose?

Mr. Bonsey: But it would be possible to do it if you took sufficient.

The Master of the Rolls: He does not poison himself.

Mr. Bonsey: There are numerous things—

The Master of the Rolls: You are not going to tell us harmless you have a dear good friend, Sir Wilfrid Lawson—that beer is a poison?

Mr. Bonsey: No, my Lord, I should hope not.

The Master of the Rolls: You would not say so, would you?

Mr. Bonsey: I should have been dead long ago.

The Master of the Rolls: If you drink any amount of something which is not a poison, how can you poison yourself? That sounds like a puzzle.

Mr. Bonsey: Then the answer is—what is a poison?

Lord Justice Kay: The Act says certain things are poisons, at any rate. We have not to determine that question, because the Act says opium and all preparations of opium are to be deemed poisons.

Mr. Bonsey: Then, my Lord, does it depend at all on the quantity, or not?

Lord Justice Kay: Not the least. The Act prohibits the sale of any quantity whatever of the things which are in the schedule, except by a qualified person.

Mr. Bonsey: Then suppose they prove that in any of these proprietary medicines there is a hundredth or a thousand part of a grain of morphine?

Lord Justice Kay: De minimis is the answer to that.

Mr. Bonsey: Then, my Lord, if that principle applies, it must come to a question of quantity.

Lord Justice Kay: The answer to that is, you come within the Act, but we shall not impose a penalty for such a trivial thing as that.

Mr. Bonsey: Then surely it is a question, of quantity if that maxim applies, because you must investigate in each case in order to see whether it contains sufficient to poison.

The Master of the Rolls: No, infinitesimal.

Mr. Bonsey: Then what is infinitesimal? In Delve's case, for instance, the analyst found that there was more than a trace, and it might be the quantity was one-fiftieth of a grain per ounce, or three-fiftieths of a grain in the bottle.

The Master of the Rolls: What sized bottle; one of those things somebody held up just now?

Mr. Bonsey: An ounce bottle, I think it was.

Lord Justice Smith: Do I understand that the bottle was sold by a grocer without the label "poison" upon it?

Mr. Crump: Yes; that is the original bottle.

Mr. Bonsey: Was there the poison label upon it or not?

Mr. Crump: No.

Mr. Bonsey: Some have, and some have not. In a great many of these cases they have put the word
“poison” on them, with a notice that they are labelled “poison” in consequence of the decisions.

The Master of the Rolls: Then they comply with the Act. Since the cases came before the court they have begun to comply with the Statute.

Mr. Crump: And are registered chemists.

The Master of the Rolls: You want to discourage them.

Mr. Bonsey: As a matter of fact it is really a trade dispute between the grocers and the chemists. One wants to get the monopoly of the trade.

The Master of the Rolls: I know.

Mr. Bonsey: I do not know that I can add more. My important points are that: first there is no evidence of the thing being a poison in this case, because they have let it pass into the open air.

The Master of the Rolls: If you drink wine and water, you do not drink wine?

Mr. Bonsey: No, my Lord: in one sense I do, in the other sense I do not. If anybody were to ask me to have a glass of wine and gave me a glass of wine and water, I would immediately reject the 2-1 mixture, that is all; I should not take it for a glass of wine. Then, my Lord, I say there is no evidence that the article sold was a poison.

Then there is the other point, that the Act was never intended to apply to proprietary medicines which are included in the word “patent” in section 16.

Mr. Moulton, Q.C., rose to address the court for the appellants.

The Master of the Rolls: What, you also; good gracious!

Mr. Moulton: My Lords, I am with my learned friend, and the point which I shall put before you is that the Lordships is the saving clause 16, says “nothing hereinbefore contained shall extend to or interfere with the business of any legally qualified apothecary... nor with the making or dealing in patent medicines, nor with the business of wholesale dealers in supplying poisons in the ordinary course of wholesale dealing.”

The Master of the Rolls: Where is that?

Mr. Moulton: Section 16, my Lord. Section 17, which comes afterwards, is of course not included in the saving clause, because it is “nothing hereinbefore contained,” so that the scheme of the Act is that the precautions provided under section 17 shall be taken, whether or not you are within the saving clause. Now we are not proceeded against for not having taken the precautions under section 17, and I need not deal with that. It may be that section 17 with its precautions, which certainly have their own force, would be a precedent, but I say that section 17 does not affect us here, because I am going to claim before your Lordships that we are free from section 16, because we come under the exemption given in section 16.

Lord Justice Smith: Patents?

Mr. Moulton: Patent medicines; that is the sole point I intend to put before your Lordships.

Lord Justice Kay: Then you must tell us exactly what the meaning of patent medicine is.

Mr. Moulton: I submit with very great confidence, whether 1 shall in the least be able to persuade your Lordsships to take the same view. I do not know that the term patent medicine has any other meaning at all than that it is another name for proprietary medicine, and, the best of my knowledge and experience it has no other meaning whatever.

Lord Justice Kay: Is there not some legislation about patent medicines? Is it not under some Act of Parliament that you have to obtain something which amounts to a patent?

Mr. Bonsey: That is the Revenue Act—the Stamp Act.

Mr. Moulton: To the best of my belief I have never, to the best of my experience, heard of Letters Patent for a medicine. What I feel pretty certain of is that the word “patent medicine” is used as a phrase in the English language. It does not mean, and never has meant, medicines for which Letters Patent have been granted; but it does mean medicines which are sold with the revenue stamp of this kind, and are always called patent medicines. It is a question of the English language, and I want to point out to your Lordships why it was that they were excluded. My Lord, this Act, if I understand it rightly, is an Act to prevent dispensing by incompetent persons. That is what it was primarily directed against. Secondly, in section 15 it will go on to insist upon certain precautions being taken in the sale of deadly articles. Primarily, and during the whole of the first part of the Act, it was against dispensing by unqualified persons who were unskilful, and I believe, if I remember rightly, the very preamble of the Act points to that as its aim.

The Master of the Rolls: You mean to say a grocer is an unskilled person?

Mr. Moulton: Yes, my Lord, but the point about proprietary medicines is that the retail dealer does not dispense it; it is all made up for him. It has a stamp, and it cannot be tampered with by him.

The Master of the Rolls: What do you mean by dispensing?

Mr. Moulton: It is not made by him; it is not concocted by him.

The Master of the Rolls: It is dispensing, not concocting.

Mr. Moulton: I am dealing with what I suggest is the aim of the Act. The aim of the Act is to prevent persons concocting medicines who are not skilful. If you will allow me to refer to some of the earlier parts of the Act, I think you will find that was the reason.

The Master of the Rolls: Do you say that a grocer, if he concocted a medicine made up from a prescriptive by a medical man—a doctor—

Mr. Moulton: He could not sell it.

The Master of the Rolls: Because he would be dispensing it.

Mr. Moulton: There he would be dispensing it, I take it, by his agent; he might be a grocer.

The Master of the Rolls: No, not by his agent. A grocer could not sell it in his shop.

Mr. Moulton: If it was a medicine made up by a properly qualified person?

The Master of the Rolls: Yes.

Mr. Moulton: But, my Lord, I do not suppose that he could unless that came under the head of proprietary medicines or patent medicines. The case which was excepted was the common case in which a retailer has nothing to do with the compounding of the medicine, and therefore his want of skill makes no difference. I am only stating my argument at the present moment. I will try to make it good, but I want to point out to your Lordships that there was a very good reason for excepting these proprietary medicines from that point of view. It makes no difference whether this is sold by a chemist or by a grocer. It comes exactly in the same way into the hands of the public. The fight here is merely a trade fight whether the highly lucrative business of transferring these things from the hands of the wholesale maker to the hands of the public shall be in two trades or in one trade. There is no difference whatever in the danger to the public when this passes from the hands of a Staggist and when it passes from the hands of a grocer. Therefore, my Lord, when you come to the question of patent medicines that are put on the market in a form in which they are already compounded, and where they
cannot be tampered with, because your Lordship sees that they have a stamp over them, they were purposely excluded from the first fifteen sections of the Act. In my opinion, they are not excluded from the 17th section.

Lord Justice Smith: Is there a duty paid on each stamp?

Mr. Moulton: Yes, my Lord.

The Master of the Rolls: Under what Statute?

Lord Justice Kay: In the Act of 44 Geo. III. there is a schedule.

Mr. Moulton: And I think 15 Geo. IV.

Lord Justice Kay: That imposes a duty on certain things put in the schedule. There is a subsequent Act of George III. which says what medicines shall be considered patent medicines. I was just looking at it.

Lord Justice Smith: What is the other Act?

Lord Justice Kay: 52 Geo. III., cap. 150: "Whereas by an Act passed in the 44 Geo. III. certain ad valorem stamp duties were imposed on divers medicines and medicinal preparations specified and inserted in the Schedule of Drugs, Herbs, Pills," and so on.

Lord Justice Smith: I do not find the words there "patent medicines."

Lord Justice Kay: I was looking at the Index to the Acts of Parliament which enumerates patent medicines.

Lord Justice Smith: Is there a patent medicine there?

Lord Justice Kay: I am looking for it.

Lord Justice Smith: I have been looking also, and I cannot find the words "patent medicine."

Lord Justice Kay: There are medicines scheduled in the Act.

Lord Justice Smith: On which duty has to be paid.

The Master of the Rolls: What is the name of your medicine?

Mr. Moulton: Balsem of anised.

Lord Justice Kay: That is not in this schedule.

Mr. Moulton: If I remember rightly, I think all medicines sold under a proprietary title come under the stamp duties, and they are sold in this form.

Lord Justice Smith: Do you know what Act would impose that duty?

Mr. Moulton: I am not quite sure of it, but I will have that examined into.

Lord Justice Kay: There is a heading here: "Medicine, Patent Medicines, Stamp Duty on," in the Index to the Acts, and the Acts mentioned are the 32 Geo. III., the 44 Geo. III., and then there is one, 55 Geo. III.

Mr. Crump: In the Adulteration of Food and Drugs Act, 36 & 39 Vic., cap. 63, patent medicines are distinguished from proprietary medicines in section 6, where a drug or food is a proprietary medicine or is the subject of a patent in force.

Mr. Moulton: It may be that sometimes the two words patent and proprietary medicines, may be used.

The Master of the Rolls: I see why this should have a stamp under 62 Geo. III. After all these enumerated things there comes a general paragraph: "All other pills, powders, and so on. " And all medical and official preparations whatsoever to be used externally or internally as medicines or medicaments for the prevention, cure, or relief of any disorder or complaint incident to or in any wise affecting the human body; made, prepared, attired, vended, or exposed to sale by any person or persons whatsoever, wherein the person making, preparing, vendering, or exposing to sale the same, hath, or claims to have, any occult secret or art for the making or preparing the same; or hath, or claims to have, any exclusive right or title to the making or preparing the same, or which have at any time heretofore been, now are, or shall hereafter be prepared, uttered, vended, or exposed to sale under the authority of any Letters Patent under the Great Seal." You see then the occult secret things and the patent ones distinguished.

Mr. Moulton: Yes, my Lord, but the phrase "patent medicine" is commonly used for both.

The Master of the Rolls: I beg your pardon, but we cannot take that, even from you.

Mr. Moulton: Then it is for your Lordships to decide, but I am admitting that is the meaning.

Lord Justice Kay: Is it the meaning of it in an Act of Parliament where such things as actual patent medicines are mentioned as patent medicines and distinguished from proprietary medicines? In section 16 the words are "patent medicines."

Mr. Moulton: My Lord, there could have been no reason why patent medicines should have been excluded.

Lord Justice Kay: I do not know. I suppose before a patent is granted the nature of the medicine would be investigated.

Mr. Moulton: But if the patent has run out, are they no longer to have the privilege of being sold? It seems very extraordinary. I can understand a distinction between medicines that are sold with a stamp like this, so that the man who actually sells them to the public has part or lot in the compounding of them. I can understand that, but it does seem to me strange to draw the line between those which are the subject of Letters Patent and those which are subject of Letters Patent which have expired. It appears to me that it could not have been a question of the patent being taken out. It must be a question of not being a case of dispensing in the ordinary sense of the word dispensing.

Lord Justice Kay: I think that would dispense with the Act of Parliament, Mr. Moulton.

Mr. Moulton: That is what I have to argue, of course. But it is quite clear that if it were sold by a chemist, and nobody says it cannot be sold by a chemist—

The Master of the Rolls: Nobody says that.

Mr. Moulton: Whether it is being sold by a chemist or being sold by a grocer, or anybody else, anybody can make them. The article is independent of the person who retails it.

Lord Justice Kay: You are first of all to be sure that any chemist would sell it. Perhaps he would not.

Mr. Moulton: We should not be here if it was not an exceedingly profitable business. The Pharmaceutical Society is a society—

The Master of the Rolls: You must not go into that, Mr. Moulton. Please do not lead us away.

Lord Justice Kay: To poison people has always been exceedingly profitable.

Mr. Moulton: Yes, my Lord, that is the reason why the Pharmaceutical Society still exists, and is its sole merit.

The Master of the Rolls: You are using enigmatical language. Do you mean to say the Pharmaceutical Society exists for the purpose of poisoning people?

Mr. Moulton: For the purpose of keeping as far as possible the monopoly of poisons in a certain set of trading people. That is the object.

The Master of the Rolls: I should think no one would go to their Annual Dinner if that were so.

Mr. Moulton: I want to call your Lordship's attention to the preamble, and some of the earlier clauses.

The Master of the Rolls: We will hear that when we come back. [The Court adjourned for a short time.]
On resuming, Mr. Moulton, continued: My Lord, I have sent for the Medicine Stamp Acts. The section has been read to you. The penalty called your Lordship's attention to section 2 of the 52 Geo. III. cap. 150. It says that "if any person or persons, whether licensed or not, shall utter, vend, or expose to sale, or offer, or keep ready for sale, whether for foreign or home consumption, etc., any packet, box, bottle, etc. and so on," mentioned and set forth in the schedule annexed to this Act, without a paper cover, wrapper, or label, provided and supplied by the commissioners of stamps, pursuant to the said Act of the forty-fourth year of His Majesty's reign, or to the Act of the forty-second year of His Majesty's reign, hereinafter recited, and duly marked, "I have been charged on such packet, box, bottle," and so on, "being properly and sufficiently pasted, stuck, fastened, or affixed thereto, so and in such manner as that such packet, box, bottle," and so on, "cannot be opened and the contents poured out or taken therefrom without tearing you would that there be, or, let us say, with patent medicines. I put it that is the ordinary meaning of the word patent medicines.

Lord Justice Kay: Your difficulty there is that in this schedule, as the Master of the Rolls has pointed out, patent medicines are distinguished expressly from the other medicines.

Mr. Moulton: My Lord, not under that particular phrase "patent medicines."

Lord Justice Kay: Yes, indeed, "prepared, uttered, vended or exposed to sale under the authority of any Letters Patent under the Great Seal."

Mr. Moulton: That is the phrase used in all of these Stamp Acts, but the term "patent medicine" is not used at all. I say, my Lord, it is exactly like this: suppose it was a sale of patent leather, would you not be allowed to say that patent leather meant a particular form of varnished leather which was once patent-ed, as if the article of commerce. The Master of the Rolls: Patent leather boots; I suppose that leather was originally patented.

Mr. Moulton: It may have been, my Lord; but patent leather means a particular article, and if your Lordships were to go to the Directory I think that there are, or a regular trade of patent medicine vendors; but these patent medicine vendors are not people who sell medicines which are the subject of Letters Patent.

Mr. Moulton: What I suggest to your Lordship is this: all of the word "patent medicine" was used in the ordinary meaning which it bears in use. The ordinary meaning which it bears in use is proprietary medicine bearing an Inland Revenue stamp. Those are called patent medicines. This was, no doubt, a clause put in to get off the opposition to the sale of persons interested.

Lord Justice Kay: Then this Act would read: "You shall not sell the poisons mentioned in the schedule unless you have a stamp upon them."

Mr. Moulton: Yes, my Lord.

Lord Justice Kay: That would make it nonsense.

Mr. Moulton: The nonsense is as great, I submit, if you exempt those which are the subject of Letters Patent. It is difficult to draw up Acts with regard to the sale of them in section 17 are just as applicable whether they are patent medicines or not; but the mischief of unskilled dispensing is got rid of when they are sold in this form. I submit to your Lordship, when you come to look at the earlier part of this Act, it is directed against unskilled dispensing.

The Master of the Rolls: Suppose a man who concocts one of these medicines sold a rough lozenge, if you like.

Mr. Moulton: Sells it wholesale?

The Master of the Rolls: No, makes it up in these bottles, and then a person without any skill makes and sells it. Mr. Bonsey says that the chemist could not tell what was in it. I do not believe him. I should like to ask you with all your skill if you could not take it to your laboratory, and tell me how much poison there was in it!

Mr. Moulton: But if you go to a chemist's shop to buy it in any quantity without a prescription, you know that nothing depends on any skill on the part of the man who sells it. What is the difference between going into Mr. A's shop or Mr. B's shop to buy it?

The Master of the Rolls: Because the chemist, if he undertakes to sell such a thing as that, ought either to analyse it—not every bottle, of course—but to analyse the sort of thing it is. If he does not, he sells it at his risk.

Mr. Moulton: There is no penalty at all on the chemist who sells this.

Lord Justice Kay: There is a penalty on his reputation.

Mr. Moulton: No more than a penalty on the reputation of any other person who sells it.

Lord Justice Kay: He would put the word "poison" on it, would he not?

Mr. Moulton: That is not distinctive. That applies to everybody who sells. I may call attention to the fact that when you come to section 16 it says: "Nothing hereinbefore contained shall apply" to this. Which comes after applies to the sale of poisons. Supposing, for instance, this ought to have the word "poison" on it when it is sold, what does it matter whether it is sold by a druggist or a grocer?

Lord Justice Kay: You might say that of every one of the things in the schedule to the Act. It must have the poison label upon it; therefore what would it matter who sells it?

Mr. Moulton: It does matter if there is any dispensing.

Lord Justice Kay: What do you mean by "dispensing"? The Act provides against selling or compounding either.

Mr. Moulton: I submit that the meaning of the Act was that nobody should do any act which implied dispensing unless by a skilled dispenser.

The Master of the Rolls: What do you call "dispensing"?

Mr. Moulton: CONCOCTING the medicine itself.

The Master of the Rolls: You say "dispensing" means concocting?

Mr. Moulton: In the same sense as the word "dispensary" is used. I am using it in that sense. I may be wrong in using it in that sense, but what I mean is this: it was intended to prevent unskilled persons mixing, or preparing by mixing, medicines.

Lord Justice Kay: Or dealing with them in any way—selling.

Mr. Moulton: Except these patent medicines, which—as they were sold in a form in which they passed into the hands of the public without the retail dealer having anything to do with their composition—
Lord Justice Kay: I do not think that evidence would help you at all, because it would only show that a very loose use of the word "patent" had obtained, perhaps even before this Act of Parliament was passed, but it does not follow that such looseness was adopted in the Act of Parliament.

Mr. Moulton: No, it does not follow, but I suggest to your Lordship that was the meaning in which the term was used. Of course the vendors of patent medicines were a very strong body. I believe they opposed this Act.

Lord Justice Kay: What importance to you is it whether it is a proprietary medicine or stamped medicine or what?

Mr. Moulton: These are proprietary medicines.

Lord Justice Kay: I know, but is it necessary for your defence that an article should have a stamp upon it?

Mr. Moulton: Yes, my Lord, it is in this way, because the medicines which are called patent medicines must be sold with a stamp.

Lord Justice Kay: There are a great many medicines which are proprietary medicines, I suppose, which have no stamp.

Mr. Moulton: No, my Lord, there cannot be.

Lord Justice Kay: Why?

Mr. Moulton: Because it would be against the Stamp Act.

Lord Justice Kay: If they are not secret preparations? Are those horrid things they advertise by the boards in the fields which we pass on the railway all stamped?

Mr. Moulton: Every one of them, my Lord, that is sold.

Lord Justice Kay: Because they are secret preparations.

The Master of the Rolls: Beecham's pills.

Mr. Moulton: I am not specially friendly to those things, but I do press on your Lordship that patent medicine is the ordinary name by which they go.

Lord Justice Kay: See what it comes to. A patent medicine according to you is a medicine which has not necessarily got the advantage of Letters Patent, but it is a proprietary medicine which has a stamp upon it, that is all.

Mr. Moulton: A medicine which passes into the hands of the public in the same condition as it left the wholesale dealer. That is the reason why, as I suggest to your Lordship, they were excepted.

The Master of the Rolls: You have to read so much into the Act of Parliament.

Mr. Moulton: The danger is exactly the same with regard to patent medicines as with regard to others.

Lord Justice Kay: There may be what are called patent medicines without any poisons in them.

Mr. Moulton: There may be, my Lord.

The Master of the Rolls: But a proprietary medicine, although it has poison in it, may be sold?

Mr. Moulton: Yes, my Lord.

Lord Justice Kay: If somebody chooses to mix two or three of the poisons in the schedule and sell them as a proprietary medicine with a stamp upon it he would be exempted by the very Act which says nobody shall sell those poisons unless he be a chemist.

Mr. Moulton: Exactly the same thing, in fact a worse, applies to Letters Patent. Suppose there is a really dangerous medicine.

Lord Justice Kay: A patent would not be readily granted for it, would it?

Mr. Moulton: Yes, my Lord, if it were useful for certain purposes. Take the case of those medicines which are used in the more dangerous forms of heart disease, which are very powerful and necessary, and are very rightly considered useful medicines. A person takes out a patent for such medicine.

The Master of the Rolls: Does he?
Mr. Moulton: I do not believe, my Lord, he does. I do not believe the word "patent" is really applied to medicines other than these proprietary ones you supposed, although anybody could with his permission actually dispense that, whether they have skill or not, and they are not interfered with by this Act, whereas, if you take the term patent to mean medicines with the composition of which the retailer has nothing to do, then it appears to me that the legislation is incomplete, although I do not defend it.

Lord Justice Kay: The legislation would be the most idiotic conceivable if that were the meaning of it.

Mr. Moulton: It seems to me, if I may say so, that if the Act does not intend to deal with all the evils with regard to poisons, but only with unskilful dispensing, it might be very reasonable to expect that skill should make no difference where the retailer is not the dispenser in the sense in which I used the word dispensing, that is, the person who makes up the medicine. What difference is there whatever in a person selling who is a grocer, or a person selling it who is a druggist? Of course I am putting before your Lordships that patent medicine is the ordinary colloquial name for these medicines. I have now shown more than that, that they are free from the difficulty of unskilful dispensing. I quite agree, my Lord, that there ought to be legislation of some kind to deal with the matter; but I submit that was not the object of this Act.

Lord Justice Kay: According to you, medicines might be made up by any person without the slightest chemical skill or knowledge; and if they have the stamp upon them, so that they may be called proprietary medicines, although they contain the most potent poisons, they may be sold by anybody.

Mr. Moulton: Your Lordship is somewhat criticising the legislation.

Lord Justice Kay: No; I am trying to show what is not within the legislation.

Mr. Moulton: Ordinary proprietary medicines are medicines made up wholesale by some person and sold by him in a form in which they are not altered. Now, the wholesale trade is specially exempted from this Act. In fact, it might be said to be an Act for precaution with regard to the sale of poisons, except in large quantities, but you can sell poisons wholesale; but you may not, as I submit to your Lordship, dispense poisons unless qualified to do so.

The Master of the Rolls: If he is confined to skilled persons who are to dispense, as you call it, then the wholesale dealer sells to them, because he cannot sell to anyone, since the others cannot sell it.

Mr. Moulton: Yes, my Lord; but he can sell to anybody.

The Master of the Rolls: If anybody will buy. But if they can only buy on the terms that if they sell they will have to pay a £10 penalty, they will not.

Mr. Moulton: What is the advantage of selling to the skilled. They have nothing to do with the medicine. It never changes its form.

The Master of the Rolls: I do not know about that. I do not say it does, but they ought to take care. I cannot accept the view that these people cannot tell what they are dispensing. They cannot.

Mr. Moulton: Might I point out to your Lordship the Act does not make chemists and druggists skilled in poisons in any way at all. It is only for the purpose of seeing that they are skilled in dispensing.

The Master of the Rolls: Skilled in what?

Mr. Moulton: In the art of making.

The Master of the Rolls: Do you mean in selling?

Mr. Moulton: No, my Lord, in taking a prescription and properly making it up; they are skilled in that. They are not to be persons who are to prescribe. They are not persons with any responsibility as to the effect of drugs. The one thing that this Act is intended to do is to provide that they shall not make blind sales of poisons.

The Master of the Rolls: The section, I think, defines chemists and druggists—"chemists and druggists within the meaning of this Act shall consist of all persons who, at any time before the passing of this Act, have carried on in Great Britain the business of a drug shop, or have been engaged in the keeping of open shop for the compounding of the prescriptions of duly qualified medical practitioners."

Mr. Moulton: Precisely what I submit; that they had been engaged in making up medicines, and that they were the persons who might make up poisons.

The Master of the Rolls: They are the persons who, by the Act of Parliament, may sell poisons.

Mr. Moulton: I know, my Lord. I submit they are the people who may not make poisonous mixtures and sell them.

The Master of the Rolls: Who may?

Mr. Moulton: Yes, my Lord; who "may" make mixtures and sell them; but I submit it was directed to secure trade skill in compounding—perhaps compounding is a better phrase than dispensing.

Lord Justice Kay: You put the word "sell" out of section 1, which says it shall be unlawful for any person to sell or keep open shop for the purpose of retailing, dispensing or compounding, etc.

Mr. Moulton: But for the exemption in clause 16 that word "sell" would be fatal to my contention.

Lord Justice Kay: Unless you can say this is a patent medicine your contention fails.

Mr. Moulton: Yes, my Lord, I quite admit that. I did not intend to put this portion of the argument on any other ground. If your Lordships come to the conclusion that I am wrong in submitting to your Lordship that the term patent medicine is the ordinary name for proprietary medicine, and that it was so meant, then I quite agree that my argument fails. But if it was intended by this Act in the first sixteen sections to secure skill in the people who compound, then there is something reasonable in saying that medicines which they do not compound, but simply pass on, were not to be interfered with.

The Master of the Rolls: You go to this extent. You say the making or "dealing in patent medicines" means making or dealing in proprietary medicines, however poisonous.

Mr. Moulton: They may be poisonous whether patented or proprietary.

The Master of the Rolls: There may be a difference. As you say, a patent would not be granted for a poison.

Mr. Moulton: It might be most useful. It might be a right patent.

The Master of the Rolls: It is against public policy to grant a patent to a man to make and sell poison.

Mr. Moulton: But, my Lord, it certainly might be a most important medicine, if it was for a special disease. You cannot be certain that the medicine will not be a poisonous medicine.

The Master of the Rolls: I see the difficulty about patented medicines as you say, because if a medicine could be patented, I suppose a physician could not write a prescription containing the same thing.

Mr. Moulton: That is the point I should have said—if it had been for the Statute Act—there could not be such a thing patented. I am quite sure an injunction would not go from this court to prevent people writing a prescription which followed a patent in order to cure a person. I am sorry to find the statutes do not recognise that there may be patents for medicines and poisons. It is all clear, but, my Lords, I will not repeat myself further.

Lord Justice Smith: Suppose a man had a patented medicine with poison in it. If I understand this Act,
a chemist selling that would have to put "poison" outside it.

Mr. Moulton: Under the 17th section.

Lord Justice Smith: And if it were under part 1 of Schedule C, it would be admissible to do so.

Mr. Moulton: Yes, and so would everybody. The grocer or anybody who could sell it and make it.

Lord Justice Smith: A patented medicine.

Mr. Moulton: Yes, because all the sections, down to the end of the 15th, are exempted in the cases of making and selling patent medicines.

Lord Justice Smith: I do not agree to that, but why do you add under section 17?

Mr. Moulton: My argument is that the 17th section applies to proprietary medicines and to those which are the subject of Letters Patent under the Great Seal.

Lord Justice Smith: I should have thought the 17th section applied to all poisons.

Mr. Moulton: Every one, because the 16th says: "Nothing hereinbefore contained."

Lord Justice Smith: I know it does.

Mr. Moulton: My case is that the precautions apply to medicines, to proprietary medicines, to medicines under a patent, to everything; but I submit to your Lordships the sections from 1 to 15, relating to the precautions which secure that there should be proper persons to dispense poisons, do not apply to medicines which are made by wholesale men.

Lord Justice Kay: I suppose that exemp- tions of patent medicines were put in because there were so very few of them that they would not be of any importance.

Mr. Moulton: I should say quite the contrary. There were so many of them, they could not get the Act through without it. It appears to me it was put in to prevent a great opposition there would have been by people who owned proprietary medicines.

Lord Justice Smith: Was it not put in to save the rights of persons who had patents and nobody else? These proprietary people had no rights at all. They had no legal rights, but patentees had.

Mr. Moulton: No, my Lord. They had no legal right, and the patentee has no right except to prevent other people making.

The Master of the Rolls: What my brother says is rather important. Anybody might make it up and sell what you call a proprietary medicine, if they could find one or another patentee.

Mr. Moulton: Quite true.

The Master of the Rolls: Then proprietary is the wrong word; there is no property in it.

Mr. Moulton: Just as much as in those called patent medicines; proprietary medicine is not by any means a correct phrase.

Lord Justice Kay: But if, under the Great Seal, an exclusive right has been granted to A to make up and sell a particular kind of medicine, the Pharmacy Act surely only means that we are not going to interfere with and take that right away from him.

Mr. Moulton: No acquires no right to do the thing under his Letters Patent.

Lord Justice Smith: He acquires a right to stop everybody else doing it.

Lord Justice Kay: I said the exclusive right.

Mr. Moulton: Therefore there was nothing requiring protection or exemption.

Lord Justice Smith: It would interfere, I mean, with the patentee.

Mr. Moulton: No more than with any other person, my Lord, a man having as much right to make a non-patented article as a patentee has to make a patented article, every bit.

Lord Justice Smith: But the others are all the world, and patentees are a special class.

Mr. Moulton: I quite see there is that difference, but the patentee has not any higher right to make its article than a man has to make what is open to all the world. I quite agree the one is a special class and the other is the whole world. It appears to me that the evil is the institutional dispensing would exist in the case of the patent medicines, whereas in the case of medicines which do not get interfered with at all by the persons who actually retail them it appears to me there was a reason for exempting them, not from the precautions which arise from the nature of the article itself, but from the precautions which deal with the skill of the person who dos the compounding. My Lord, I will not repeat myself; that is my view with regard to that point.

The Master of the Rolls: Do you know what the examination is of a pharmaceutical chemist?

Mr. Moulton: It is an examination in the Pharmacopoeia, in making up medicines. I believe it is a practical examination.

The Master of the Rolls: It says "competent skill and knowledge."

Mr. Moulton: I believe that chemists are not allowed to prescribe.

The Master of the Rolls: It says, "The examination aforesaid shall be such as is provided by the Pharmacy Act."

Mr. Moulton: The doctors attack chemists, and will not allow them to prescribe. It is only a question of skill in compounding, in making up the medicines of the duly qualified practitioner.

The Master of the Rolls: I wanted to know if the examination did not go further than that. What is the Pharmacy Act?

Lord Justice Kay: It must include the quantities of the drugs and their effects on the human frame.

Mr. Moulton: I cannot tell, my Lord. I know it includes a great deal of knowledge of the contents of the Pharmacopoeia.

Lord Justice Kay: And the quantity of morphine that would be a fatal dose, and so on.

Mr. Moulton: I do not know whether it includes doses or not; I know it includes such things as questions as to particular preparations in the Pharmacopoeia.

Mr. Crump: It is mentioned in section 8 of the original Pharmacy Act. The examination under the provisions of this Act includes an examination in knowledge of the Latin language, in botany, in materia medica, and in pharmaceutical and general chemistry. That is in the Act of 1852.

Mr. Moulton: Now, my Lords, I have only one other point to put before your Lordships, and that is the question of the curious terms, "compounds" and "preparations." I submit it cannot be meant that any fraction of poison being present in a mixture makes that a preparation of the poison. If your Lordship will kindly look at the schedule of the Act, there is, for instance, prussic acid in the first part; then in the second there is essential oil of almonds, unless deprived of its prussic acid. That recognises that essential oil of almonds will have, as it certainly has, a proportion of prussic acid in it, and yet it comes under part 2.

Lord Justice Smith: That is not so virulent as the other.

Mr. Moulton: No, and it is not subject to the same restrictions.

Lord Justice Kay: But it is a compound, you see, because they speak of depriving it of its prussic acid.

Mr. Moulton: What I point out is this: the mere fact that prussic acid is present in a fluid cannot bring it under the first head as being prussic acid, because if it did, essential oil of almonds not deprived of its prussic acid would also have to be under the first head. So, my Lords, I submit that the first
head means those things isolated, such as prussic acid.

Lord Justice Smith: Would not essential oil of almonds not deprived of prussic acid be prussic acid? Mr. Moulton: There would be prussic acid in it. I do not know what percentage.

Lord Justice Smith: It is a very violent poison.

Mr. Moulton: It is. Probably there would be, to give a guess, 4 or 5 per cent. of prussic acid in essential oil of almonds. I should doubt whether it would be stronger than the Lord; there would be prussic acid in it. I do not know what percentage.

Lord Justice Smith: It is a very violent poison.

Mr. Moulton: It is. Probably there would be, to give a guess, 4 or 5 per cent. of prussic acid in essential oil of almonds. I should doubt whether it would be stronger than the Lord; there would be prussic acid in it. I do not know what percentage.

The Master of the Rolls: It seems to me terrible to suppose that if you put some of these things in with other things, it gets rid of them altogether. Look at corrosive sublimate.

Mr. Moulton: If corrosive sublimate was present in very minute quantity—

The Master of the Rolls: In infinitesimal quantity. If you say you found an infinitesimal trace, we should know there was none.

Mr. Moulton: I submit it must be more than that otherwise you cannot understand essential of almonds, not deprived of its prussic acid, being put in part 2, and prussic acid being put in part 1.

Lord Justice Smith: Is not essential oil of almonds a preparation of prussic acid?

Mr. Moulton: No, my Lord; it is got from the almonds themselves.

Lord Justice Kay: It is the substance from which prussic acid is made.

Mr. Moulton: Originally, I believe. We get it by roundabout methods now, which are cheaper.

Lord Justice Smith: Supposing you poisoned a person with essential oil of almonds, would you say he died of prussic acid?

Mr. Moulton: He would die of prussic acid poisoning.

Lord Justice Smith: Then the question would be whether it was prussic acid?

Mr. Moulton: That is what I want to point out to your Lordship. It is clear that the essential oil of almonds, not deprived of prussic acid, is only liable to the precautions in part 2, because it is specially stated.

Lord Justice Smith: If it is deprived of its prussic acid?

Mr. Moulton: If it is not deprived; of course if it is deprived of it, it is not a poison at all. It is out of the schedule altogether.

Lord Justice Smith: Yes, I see.

Mr. Moulton: I want to point out what I submit to you is the meaning of these schedules. I submit a poison is that of which a small quantity is fatal. Now if you take a strong poison and mix it with a very large amount of other matter it then becomes bulk for bulk, only equally poisonous with a thing which is far less poisonous. Let me give your Lordship this very odd case of essential oil of almonds which has prussic acid in it. The dose of prussic acid which is fatal is infinitesimal compared to the dose of essential oil of almonds. Take the next case, opium, if you look in schedule A you will see "all poisonous vegetable alkaloids." Opium contains many poisonous vegetable alkaloids. If you isolate them, their poisonous characters fall out of the rank of being terrible poisons which in very small quantities produce death, then they may fall into the second class.

Lord Justice Kay: It strikes me that your best argument on section 17 itself is that if the other side be right in the extreme argument they will urge against you, no chemist could sell any medicine in which a small part of these poisons enters without warning the buyer. Mr. Moulton: The word "opium" must contain a poisonous vegetable alkaloid.

Lord Justice Smith: Opium would only want the word "poison" outside, would it?

Mr. Moulton: That is all, whereas opium, because it contains a poisonous vegetable alkaloid, would require to be under the first class. I submit the first class means that those poisonous principles, when isolated, are immeasurably more dangerous than the stuff from which you get them. There is a most curious example, my Lord, of that in one of the additions to this schedule. Strychnine is put down in part 1 of the schedule.

The Master of the Rolls: Then chemists who, when you send a prescription of a physician to them, and they make it up and put "poison" on the bottle when they sell it, are doing what they need not do, lending to you?

Mr. Moulton: It depends, my Lord; I think they are obliged to do it.

The Master of the Rolls: They do. You see it in every house into which you go. They put "poison" on the bottle which they make up from the prescription of the physician, so that the people of the house should not give it indiscriminately.

Mr. Moulton: Your Lordship is quite right—"Nor shall any of the provisions of this section apply to any medicine supplied by a legally qualified apothecary to his patient."

The Master of the Rolls: Section 17.

Lord Justice Kay: Section 17 requires "poison" to be put on the bottle.

The Master of the Rolls: They do it, you know. Mr. Moulton: They do, but they are not obliged to do it if they are druggists.

The Master of the Rolls: That is what I put to you. If you read section 17 in its simplicity, they are right in doing what they do.

Mr. Moulton: Yes, my Lord.

Lord Justice Kay: You say if this were made up by chemists they need not put "poison" on the bottle?

Mr. Moulton: No; they need not.

Lord Justice Kay: Why not?

Mr. Moulton: Because it is applied to a medicine supplied by a legally qualified apothecary to his patient.

Lord Justice Smith: I think the complaint is not under section 17.

Mr. Moulton: I know we should, but the complaint is not under section 17.

Lord Justice Smith: I think the complaint is not under section 17.

Mr. Moulton: I think the complaint is not under section 17.

Lord Justice Smith: I think the complaint is not under section 17.

Mr. Moulton: I think the complaint is not under section 17.

The Master of the Rolls: He has only to put "poison" when he sells poison. Your argument has been throughout that in this case he does not sell poison.

Mr. Moulton: I was dealing now with the question of what was intended really to be the meaning of the word "poison." I was dealing with the argument that if there is any of the poison present you must look upon it as a case of selling that, and I point out that it cannot be so, otherwise these distinctions between the first and second part of the schedule would be contradictory, because you would find things which are distinctly said to be under part 2, which according to that canon of construction would necessarily be under part 1.
Lord Justice Smith: I do not follow that. Prussic acid must be under part 1, must it not?
Mr. Moulton: Yes, my Lord.
Lord Justice Smith: There is nothing about essential oil of almonds in part 1 at all.
Mr. Moulton: No.
Lord Justice Smith: But essential oil of almonds not deprived of its prussic acid is under part 2.
Mr. Moulton: Yes, and it contains prussic acid.
The Master of the Rolls: That is the nature of the thing, that is not a compound.
Mr. Moulton: Therefore the presence of prussic acid will nearly bring the thing into the first part of the schedule: that is what I mean.
The Master of the Rolls: That is not prussic acid compounded with something else.
Mr. Moulton: Yes, my Lord, with all respect.
The Master of the Rolls: It may be, chemically.
Mr. Moulton: It is really a mixture; you can separate the two parts.
The Master of the Rolls: Who mixes it?
Mr. Moulton: It is mixed in the plant. Take this very case. We are accused here of selling morphia.
As a matter of fact, there is no morphia put in here. There is opium put in, but in order to find out whether there is no morphia we must do a series of tests for a definite alkaloid, and he finds morphia. They say there is one-tenth of a grain, but nobody could say—it would not be true—that you had isolated morphia, and then put in one-tenth of a grain. It is here, because it is part of the opium which was used. Of course, it is much more easy to test for the presence of morphia than opium.
Lord Justice Kay: It would be just as wrong to use opium.
Mr. Moulton: I want to point out that it cannot be taken in this Act that the mere presence of something in the schedule is sufficient.
The Master of the Rolls: Suppose it is opium?
Mr. Moulton: That would be in part 2 of the schedule.
The Master of the Rolls: Then you would be liable to the penalty.
Mr. Moulton: Then it ought to be labelled "poison."
I admit.
The Master of the Rolls: Can anybody but a chemist sell it?
Mr. Moulton: Now I am going on to that.
Lord Justice Kay: If you do not get it out under "poisonous medicine", it is all the same.
Mr. Moulton: If I do not get it out under patent medicine I can only get it out under the next argument, which is one step further. I have pointed out that the mere presence of morphia does not bring it into the class, although morphia is in the first class, because we clearly see that pure opium can be sold under the second class. I submit just in the same way that where the opium is only a small proportion, only one ingredient, it would not come under the phrase "opium and all preparations of opium or poppies." I submit that refers to things as are well known in the Pharmacopoeia.
Lord Justice Kay: Lundamun?
Mr. Moulton: Lundamun would be distinctly a preparation of opium. There are certain pharmaceutical preparations of opium which are used as forms in which opium may be put into medicines, but I submit, my Lord, that one ingredient, a small ingredient of medicine would not necessarily bring it under part 2 of the schedule. Otherwise, my Lord, anything that has got any opium in it would come under it—What is opium? I do not know.
You have preparations of poppy heads, and those things, you have poppy water and everything of that kind, which would at once be said to be poisons.
Lord Justice Smith: Was it not the intention of the Act that these things should be dealt with by the chemist, and not by the grocer?
Mr. Moulton: Anything which was substantially, I was going to say seriously, poisonous.
Lord Justice Smith: I do not see why a grocer shall sell this stuff any more than a druggist should sell bread or sugar. The main object of this Act was to confine these poisons—I use the words used in the Act—to the person who was skilled. I know your argument about patents.
Mr. Moulton: Yes, my Lord, I will not go over that again. Take arsenic and its preparations. It may be a very improper thing, but certainly arsenic is perpetually used as a dye. It may be used, for instance in some of our beautiful green colours, but I doubt very much whether it was intended that you shall not sell a green silk unless you were a druggist, because arsenic is often used very harmlessly.
Lord Justice Smith: In silk?
Mr. Moulton: Yes, my Lord, in dyeing silk.
Lord Justice Smith: Or in wall-papers?
Mr. Moulton: Yes, my Lord, sometimes it is used badly, and sometimes well, but it was never intended that the mere existence of arsenic in articles, if it was in such a form that it became poisonous, should be interfered with.
The Master of the Rolls: We all know that this Act of Parliament is not applicable to wall-papers.
Mr. Moulton: I carry it a little too far perhaps, my Lord, if I say that, but is it not quite easy to imagine many cases in which there are small quantities present, which do not render the article poisonous. They do not render it what I may call substantially poisonous; that is, a thing of which a very small quantity will cause death, which is the definition of a poison. These are not all the poisons. These do not include one hundredth part of the things which, if taken, will produce death, but they are the things which if taken in small quantities will cause death. There are cases of death from petroleum, and death from such things as Condyl's fluid. All those things are poisonous, but they do not need to be specially guarded against, because they are not so poisonous that very small quantities will produce death.
Lord Justice Smith: They are not within the Act, are they?
Mr. Moulton: No, they are not. I say, just in the same way, if you take something which is in the Act, and put it into such a shape that it falls into the category of non-poisonous things—that is, things of which a considerable amount is requisite to cause death—I submit it was not intended that those should be within the Act.
Lord Justice Smith: I put it to you before, and I should like you to answer it if you can. Suppose a man half filled a bottle with chloroform and half with water and sold it, would he be selling chloroform or not?
Mr. Moulton: Yes, my Lord; if I may say so I should put it this way, I should say that is substantially a preparation of chloroform. If he fills the bottle half with water, and then fills it up with chloroform, does he sell chloroform?
Mr. Moulton: With those proportions I should think your Lordship would probably say he does.
Lord Justice Smith: One other word, there is nothing about proportions in this Act.
Mr. Moulton: No, my Lord.
Lord Justice Kay: You could not deny that if chloroform were sold in such very small proportions as to be innocuous, it would still be infringing this Act.
Mr. Moulton: Because chloroform in any form is an exceedingly violent agent. Let me give your
Lordepin an example. Chloroform mixes very readily with alcohol. Supposing a man sold alcohol with a small fraction, say 1 per cent., of chloroform in it, I should very strongly contend that that was not selling chloroform.

Lord Justice Smith: I should like to catch him if I could.

Lord Justice Kay: Do you mean to say that a man who compounded that would not be infringing this Act?

Mr. Moulton: I certainly think the man who compounded a thing like that would not be. I should think he was not really selling chloroform. It would be chloroform under the Act practically not to have the properties of chloroform. Let me give your Lordships an example. Chloroform is a very excellent solvent; it is used by painters in dissolving away their paint when they want to clean it off their pictures, and you can easily imagine that it might be used as a solvent for dissolving certain materials, and mixed with these things in a very small proportion. What you would sell there would contain chloroform, but would not be called chloroform, would not be fairly called a preparation of chloroform. That is what I submit. You have to look at the ultimate form, and not merely say what you are going to sell. Take the same case, phosphorus, which is a very bad poison; you cannot sell bread without selling phosphorus in it. Nobody would say that it is phosphorus, it is in such very small proportions that the characteristics of phosphorus are not dominant. Therefore, I say, my Lord, even if these things are present, they are not present in such a form that the result is poisonous. They are not in anything like the same category as the original thing.

Lord Justice Smith: Curiously enough as regards this argument the words are "they shall be deemed to be poisons"—that is whether they are, or are not.

Mr. Moulton: "Deemed to be poisons."

Lord Justice Smith: Then chloroform, whether it kills or not, shall be deemed to be a poison.

Mr. Moulton: That is, to be brought within the Act.

Lord Justice Smith: Section 2.

Mr. Moulton: "Deemed to be poisons within the meaning of this Act," that is, the Act applies to them. That is what I am contending before your Lordships, that when you take these things, and they are sold as they are, not with any such modification as is sufficient to make them poisonous, then they are still within the Act.

Lord Justice Kay: The very fact that the Act has a limited operation, and is confined to certain things specified, or that may be specified afterwards under the provisions of section 3, shows I think that you ought to give a wide interpretation to those things.

Mr. Moulton: I should 'put the argument almost the other way, that it is only when they are in their strength that they are worse than hundreds of other things that are outside, and therefore when sold in such form that they do not manifest their strength, that they are then far less poisonous than things which may be sold without any restriction at all.

Lord Justice Smith: You want to read into this part of the Act "so long as they are poisonous."

Mr. Moulton: Yes, my Lord, if they are so much altered by being mixed with a very large quantity of other things.

Lord Justice Smith: You want it to read, "the several articles named or described in the schedule (A) shall be deemed to be poisons so long as they are poisonous."

Mr. Moulton: No, so long as they are sold as they are. The question is whether you are selling arsenic, we will say, when you are selling a mixture of which it is a very small ingredient.

The Master of the Rolls: As to that part of your argument, Mr. Justice Collins quotes against it the case of Berry v. Henderson, in 1870.

Mr. Moulton: He held that the presence of a very small quantity did not make to a difference.

The Master of the Rolls: He said if poison was one of the ingredients of what was sold, then it was within the 17th section.

Mr. Moulton: In what case was that, my Lord?

The Master of the Rolls: That is in Berry v. Henderson, which refers to the present case. He quoted and then you the decision of Mr. Justice Lush and Mr. Justice Hutton in Berry v. Henderson. There they sold prussic acid mixed with rose-water, and did not put "poison" on it. The point was argued, just what you are arguing, and they held against it. Then it was held he did not put the name of the poison aforementioned.

Mr. Moulton: Mr. Justice Collins held what I am contending for, that the thing to be a poison must be a poisonous thing.

The Master of the Rolls: No, he held just the contrary. In Piper's case, do you mean?

Mr. Moulton: On page 696 he seems to me to hold so.

The Master of the Rolls: "Held that the prohibition of the Act against the sale of poisons by other than registered chemists was not confined to the sale of scheduled poisons in their simple state, or preparations of such poisons, but extended to the sale of a compound containing a scheduled poison as one of its ingredients." He held the contrary. We were told that to find in your favour we must over-rule the Pharmaceutical Society v. Piper.

Mr. Moulton: It is not necessary, my Lord, that your Lordships should go so far as that, because what I am contending for before your Lordships is this: I do not say you may not put other ingredients in a poison and yet bring it within the Act. What I do say is that if you put such ingredients, that the poison ceases to retain its qualities as a thing poisonous in its entirety.

The Master of the Rolls: Forgive me for saying that is a distinction which is too fine for me.

Lord Justice Kay: What it comes to, Mr. Moulton, is this: you may compound in one bottle with some other ingredients such a small quantity of poison as to be comparatively innocuous, certainly not enough to kill, and then you may sell a dozen bottles of that, and he may take them all and it would kill.

Mr. Moulton: That is perfectly true.

Lord Justice Kay: That is the way to destroy this Act of Parliament altogether.

Mr. Moulton: You could do it exactly in the same way with regard to a chemist; a man could commit suicide by going into a chemist's instead of going into a grocer's. Surely there is no great distinction.

The Master of the Rolls: As far as I understand your argument, if a poison was one of the ingredients of the compound they do not sell poison.

Mr. Moulton: My Lord, if all that is stated is that the poison is present there, I submit it is not sufficient. Poison must be present there so as to make the thing itself poisonous.

The Master of the Rolls: If you say that you give yourself up in this case, because the County Court judge has held that the quantity is sufficient to kill a child, I suppose a child is a human being. He says it probably would kill a baby.

Mr. Moulton: I submit, my Lord, that would not be sufficient, otherwise you could buy nothing in wholesale quantities.

The Master of the Rolls: We do not give wholesale quantities to a baby, you know.
Mr. Moulton: Of course a medicine has to be given in doses, and the amount that there is in a dose is extremely small. Can it be said that if sold in bottles of half the size it would make any difference? The Master of the Rolls: Forgive me, I thought I was trying to follow your argument. Now you tell me I did not understand it; then I did not.

Mr. Moulton: I am very sorry, my Lord. I do not say the mere presence of other matters besides poisons takes it out. The Master of the Rolls: I thought you did say so. Mr. Moulton: I have submitted, my Lord, that the mere presence is not enough.

Lord Justice Kay: If I follow your argument, if a grocer took laudanum and diluted it so that in the bottle he sold there was not enough to kill anybody, even a child, he would not be infringing the Act of Parliament.

Mr. Moulton: My Lord, if very dilute I do not suppose he would be. For instance, he might use poppies.

The Master of the Rolls: Mr. Justice Collins says he was impressed with that for a time, but the impression broke down when he began to consider how an earth anybody could administer the Act if that were so.

Mr. Moulton: I think Mr. Justice Collins came to the conclusion in that case, that it was poisonous in its entirety, and the consequence was he thought the change was not sufficient.

The Master of the Rolls: If you admit that you are gone in this case, because it is held by the County Court judge as a matter of fact, and we cannot overrule his finding of fact—that in its entirety the article was poisonous.

Mr. Moulton: If that means the contents of the bottle, and if your Lordship thinks that is the issue before your Lordship, I cannot contend against that which is a question of fact.

The Master of the Rolls: I do not adopt that as the true reading of the Act, but I say if that is what you mean you are done.

Mr. Moulton: I submit there is so little poison compared to the bulk of the article, that the court may fairly say it is not even opium or a preparation of opium or of poppies. If it is not, then I submit it is not within the Act at all.

The Master of the Rolls: You are on the other side, Mr. Crump.

Mr. Crump: Yes, my Lord, the first argument by my friend Mr. Moulton is, that this is a patent medicine within the exemption of section 16. Now the legislature with regard to the Stamp Act my friend referred to, contains a reference to two species of medicine, I mean the 25th Geo. III., c. 79, section 14.

The Master of the Rolls: Was that argument used in the court below?

Mr. Crump: No, my Lord, it was not relied on.

Lord Justice Smith: Oh, yes; it was dealt with.

Mr. Crump: I do not think it was relied on or decided.

Mr. Bonyon: Oh, yes; it was relied on and decided.

Mr. Crump: Not in this case.

Lord Justice Smith: In Piper's case I mean.

Mr. Crump: Oh, in Piper's case, but not in this case. As regards the intention of the Legislature it is using the words "patent medicine," I refer to the fact that in the Act of George III. there is a distinct reference made in the same section of the Act (section 14) to articles exposed for sale under the authority of Letters Patent under the Great Seal, and also to what they refer to as sold "by any public notice, advertisement, or by written or printed papers or handbills, held out or recommended to the public by the makers, proprietors, or vendors thereof as nostrums or proprietary medicines." Now, my Lord, that distinction is specific there, so that it was clearly before the Legislature when they passed the Pharmacy Act. Then, after the passing of the Pharmacy Act, which is the 31st and 32nd Vic., comes the Adulteration of Food and Drugs Act.

Lord Justice Smith: You have Letters Patent also mentioned in the 32nd George III. Mr. Crump: I think it is so as well—c. 150, section 2.

Lord Justice Smith: Now what Act are you referring to?

Mr. Crump: The Pharmacy Act was the 31st and 32nd Vic., and then you have the Adulteration of Food and Drugs Act, 38 and 39 Vic., cap. 63. By section 6 the Act is not to apply where the drug or food is a proprietary medicine, or is the subject of a patent in force, and is supplied in the state required by the specification.

The Master of the Rolls: Where is that—in the Stamp Act?

Mr. Crump: No, my Lord, in the Food and Drugs Act.

Lord Justice Kay: It contrasts proprietary medicines with patent medicines.

Mr. Crump: Before the passing of the Pharmacy Act you had the Medicine Stamp Act, recognising medicines which were patented and medicines which were proprietary.

The Master of the Rolls: What is the Food and Drugs Act?

Lord Justice Kay: That is an analyst's Act.

Mr. Crump: It is for the prevention of the adulteration of food and drugs, and it says the Act is not to apply where the drug is a proprietary medicine, or is the subject of a patent in force.

The Master of the Rolls: They put them there into the same category, but use different terms.

Mr. Crump: The word is "or."

The Master of the Rolls: It is not to be applied to two things.

Mr. Crump: It is not to be applied to either.

The Master of the Rolls: That puts them in the same category.

Mr. Crump: It makes that Act cover both those classes of drugs. The observation upon this is that in the Medicine Stamp Acts of George III. you have a reference made to Letters Patent, and also to nostrums or proprietary medicines. The Master of the Rolls: They are both stamped.

Mr. Crump: Yes, my Lord, one is under the Great Seal and the other is not; they are both to be stamped for revenue purposes.

The Master of the Rolls: So far as the Stamp Act is concerned they are both stamped.

Mr. Crump: That is for fiscal purposes they are both stamped.

The Master of the Rolls: There again it puts them both into the same class as stampable things.

Mr. Crump: Undoubtedly.

The Master of the Rolls: But it is not all proprietary medicines, it is only those specified.

Lord Justice Kay: There are schedules in that Act. Mr. Crump: If they are offered as nostrums or proprietary medicines, or as specifics, or otherwise—that is the definition of them—for the prevention, cure, or relief of any such disease.

Lord Justice Kay: What are you reading now, the Stamp Act?

Mr. Crump: Yes, my Lord.

Lord Justice Kay: Does it not give a list of medicines that must be stamped?

Mr. Crump: No, I think not.

The Master of the Rolls: It gives a list, but goes on, after the list of named things, to give this description of things.
Mr. Crump: The Act of 25 Geo. III., c. 78, I am using simply for the purpose of showing that the Legislature had in its mind two classes of medicines, nostrums and proprietary medicines, and medicines the authority for the sale of which is granted by Letters Patent under the Great Seal. Now you come to the Pharmacy Act, which gives protection only to medicines that are permitted by the Secrety Act, and which comes a few years afterwards, gives an exemption in favour of proprietary medicines, and also patent medicines, and says the Act shall not extend to either. That clearly indicates, if anything can, that the Pharmacy Act was intended to extend only to patent medicines, and I can only think it was done in this sense, that a specification has been furnished which would show the contents of the medicine; that specification was to show the contents of the medicine, and would be passed under the Great Seal. I hold in my hand a complete specification in that form, which passed the Great Seal so recently as 1892, and there you have an attestation by the inventor of the ingredients in the patent medicine.

The Master of the Rolls: Let me see that.

Mr. Crump: I may say as a fact that the medicine contained a scheduled poison under the Pharmacy Act, and quite recently the patent has been revoked to-day. Lord Justice Kay has revoked it. It has been revoked so far as it authorised laudanum in the compound—I am told it has been revoked entirely.

The Master of the Rolls: I see it is a new medicine or compound for the cure of cholera.

Mr. Crump: Yes, my Lord; I say, of course, that makes a very great distinction.

Lord Justice Kay: Mr. Justice Collins refers to that in Piper's case. He says that one of the main reasons for exempting patent medicines as distinct from others is because in the case of a patent medicine there is a specification to which all the world can refer to see what a medicine is made of.

The Master of the Rolls: On what ground has this been revoked? Are you sure it was because it has laudanum in it?

Mr. Crump: So I am instructed, my Lord.

The Master of the Rolls: Was it not because it was nonsense? Is not this sold by an old lady who says: "The object of this invention is to provide a combination of drugs for the treatment and cure of cholera. With this purpose in view I mix together so as to make up an 8 oz. bottle the following ingredients: Sal volatile, 2 oz.; pepper-twine, 5 oz.; the old ladies will like that I am sure, "spirits of camphor, 2 oz.; laudanum, 2 oz. The required dose to be taken in hot water sweetened with sugar, or if hot water is not readily available, cold may be used. The proportions may be varied with the quantity of liquid to be manufactured."

I should say this was put an end to because it was absolute nonsense.

Mr. Crump: Possibly on all grounds, my Lord. I am only telling you what my instructions are. The point has been taken in Piper's case and suggested here in argument, where you have a patent medicine you have the ingredients declared. It is under the Great Seal authorised, but in the case of proprietary medicines it would be monstrous that anything a man chooses to call a proprietary medicine might be sold.

The Master of the Rolls: They are secret.

Mr. Crump: They claim them to be. The ingredients are professedly unknown. All a man has to do is to pays a little to the Registrar stamp, put them on the label, that he is then entitled to sell it, however poisonous. I submit the argument is one which cannot possibly be supported. The plain words of the Act of Parliament, as was held in Berry v. Henderson, and the plain scope of the Act of Parliament according to Mr. Justice Lush, is to exclude all preparations of scheduled poisons—all medicines which include a poison.

The Master of the Rolls: "Preparation" in medicine and chemistry is a peculiar word, is it not? Is not preparation making up the prescription?

Mr. Crump: No, my Lord, I think not; that might be compounding; a preparation is a medicine compounded by the manufacturer, and the Society which I represent, under the powers given it by the Act of Parliament, has gone somewhat beyond the schedule in the last Pharmacy Act. They have included preparations of prussic acid, and amongst other things preparations of morphia, so that you have an extended classification of those things which are to be deemed poisons within the Act. What I submit is—it is the shortest possible contention—that when this Act says that an unregistered person shall not sell a poison as defined by the Act, he offends against the Act if he sells a medicine containing a scheduled poison. My Lord, that is a short statement of the point as to ingredients was dealt with by Mr. Justice Lush. He says this at page 303 of the five Law Reports, Queen's Bench; he is dealing with the exception in section 17—"The first part of the section, the enacting part, applies to scheduled poisons enumerated in the first schedule. The poisons enumerated is prussic acid. I observe that the schedule seems to treat all the poisons as sold in their simple state." That is the exception all through this case, that the poison must be sold in its simple state, or that it must be a poison per se. I observe that the schedule seems to treat all poisons as sold in their simple state, or in some form of preparation alone; and it does not appear to contemplate any of them being mixed up with any other ingredients—it applies to them pure and simple.

The Master of the Rolls: We need not trouble you any more. Do you wish to comment on what Mr. Crump has said, Mr. Bosney?

Mr. Bosney: There is only one point I wish to make with regard to what Lord Justice Kay said just now, as to the schedule in the Medicine Stamps Act. Proprietary medicines are not confined to those scheduled in the Act; they are all medicines under the Act of 52 George III., "and all other medicines," and so on, prescribed for any diseases. I do not know that I wish to add anything to what I said before.

Judgment.

The Master of the Rolls: I think this appeal must be dismissed. It is an appeal against the decision of the Divisional Court, which determined an appeal from the County Court judge. With regard to any fact in the case, we are not authorised to depart from the finding of fact found by the County Court judge. There is no appeal against any finding of fact. There must be made, therefore, that in the article if you like, or the bottle or phial which was sold by the defendant in this case, there was one of the poisons named in the schedule to the Act of 1868. We do not know what all the other ingredients in this bottle were, but we know that one of the ingredients was one of the poisons named. We know that there were several other ingredients, but I think we do not know what they were, or the quantities of them. The court has held that the defendant has made himself liable to the penalty named in the Act, by selling this phial of medicine, it being admitted that the thing sold was a medicine; and he was held liable to the penalty because several other ingredients, but I think we do not know what they were, or the quantities of them. The court has held that the defendant has made himself liable to the penalty named in the Act, by selling this phial of medicine, it being admitted that the thing sold was a medicine; and he was held liable to the penalty because the said medicine was sold, and therefore the question is, must Mr. Justice Kent and Mr. Justice Lush hold that there was a scheduled poison in the phial? Now arguments have been addressed to us on the two points which we have to decide. It is said that he did not sell the poison mentioned in the schedule. If that
is not prevented by having mixed with it other ingredients, it is clear that he sold poison; he sold a particular part of this compound, which was poisonous, and if he sold poison, he is liable to the penalty, not being a person entitled to sell poison. Now, the argument is this, you have mixed this poison with other ingredients; you have not done anything to it which alters its chemical nature, you have left it still with its chemical nature in it, but have mixed it with other things. Does that in ordinary language, turn a poison into a bottle of wine cease to be a poison? Or does poison put into a cup of tea cease to be poison? The ordinary way by which in the old days people were poisoned, from cardinals downwards, was to put something into what they were going to drink. That something was poison, and it was never said, until we had skilled advocates to say it, that because the people who wanted to poison a cardinal put poison in his wine, therefore it was not poison. Wine could not poison him. Then what did poison him? Why, the poison that was in the wine. So it is clear, —and I know that the learned, for reasons which I will alter the nature of things—that when poison is put into a medicine, and a person sells the medicine, he sells the poison that is in it. Then he has sold poison. There is nothing in the Act of Parliament that I can see, reading it in its ordinary language, which says that if a person sells a medicine containing or covered up other things, though you may not sell poison by itself. There is nothing in the Act which says that. This argument was used—as Mr. Justice Collins says—with great skill and great power, and I do not doubt it from what we have heard to-day, for we have heard the same counsel who argued that case before him. But Mr. Justice Collins has another point which he gives, to the conclusion that I have come to, viz., that you sell poison, if you sell it without its nature being altered, although you do sell it mixed up with other things. I cannot see any answer to that view. I cannot appreciate the sufficiency of the argument against it, and, therefore, I think that this person did sell poison. Then we are, of course, met with the infinitesimal argument. But the meaning of the word infinitesimal when used in a court of law is that if a thing is so small that the court will treat it as such; while this court means by infinitesimal is that we treat it as something which is not really without limit, or infinitely small. In Latin, infinitesimal if you talk of it in English; but de minimis in Latin, when construed into English, means as infinitesimally small that the court will not take any notice of it. Therefore, this person did sell the poison named in the schedule A, and in the second part of the schedule. Then it is said: Ah, but he is except by reason of this, that he sold a patent medicine! Both the learned counsel who argued this have been telling us a great deal about the knowledge of patent medicines in the trade or amongst other people. I do not know whether they mean the people who make up medicines or the people who sell them—they say that all proprietors of medicines, and the vulgar name of which is "quack" medicines, are known by the name of patent medicines. In the first place I do not accept the statement of fact. I doubt it extremely. But in the second place it seems to me wholly immaterial. We have to construe an Act of Parliament. Whether we accept the arguments in the main, in the Acts of Parliament which have been dealing with this very subject matter, distinguishing between proprietary medicines, secret medicines, and patent medicines, and when you come to this Pharmacy Act and find that it has dealing with only one of those phraseologies, viz., patent medicines. I do not think that, construing this Act of Parliament according to ordinary canons and construction, you must say that it applies only to patent medicines, using that term in the sense of medicines which have procured a patent under the Great Seal. On both points I agree entirely with Mr. Justice Collins' judgment in the Pharmaceutical Society. The concern is that no one must be disciplined upon Berry v. Henderson, decided by Mr. Justice Lush and Mr. Justice Hannen. We must over-rule both those cases in order to allow this appeal. We could, of course, over-rule them, but I am of opinion they are both right. We cannot over-rule them, and, therefore, the appeal must be dismissed, the court and jury having decided in the case before them, when the case was before them, and they are the judges in this case; and I must say, it is a very good case. The learned Lord Justice Kay: The Pharmaceutical Society in this case had brought an action against the defendant, who is not a chemist—not one of the persons authorised to sell poisons under the 31 and 32 Vict. c. 121—and the Society had brought the action for the penalty which is imposed by the 10th section of that Act in these words: "any person selling poison otherwise than is herein provided, shall," &c., "be liable to a penalty," and so on. The facts of the case, so far as material, are these. The thing sold is what I suppose would commonly be called a "quack" medicine—balsam of peru. What is a quack medicine? It is precisely that. We are not told what the bottle contains, but the Society told us that each bottle contained one tenth of a grain of morphine, and what the County Court judge said in his finding on the facts, which is conclusive upon us, was this: "It was said, indeed, that it might be fatal to an adult suffering from certain diseases, but except under those special conditions I do not think that the evidence established that the contents of the bottle if taken at once would ordinarily be fatal or even injurious to adult life. In the case of children, however, it was stated that the evidence given on behalf of the plaintiff, that if the whole contents of the bottle were taken at once by a child in ordinary health it would certainly be injurious and might be fatal, and to an infant probably fatal. This evidence was not contradicted or seriously impugned by the witnesses" called for the defence, and in my opinion I ought to accept it as true." (See Pharm. Journ., liii., 708.) Therefore, this is not a case in which the maxim de minimis applies at all. I can quite understand that, although a case might otherwise be within the Act, if the proportion of one of the poisons mentioned in the schedule were so exceedingly small as to be perfectly innocuous or comparatively so, and the defendant might sell by that maxim de minimis non curat legem might possibly apply to an action of this kind; but this is not a case of that kind. Now the first argument was, this is not a sale of morphine, because it is only a sale of a composition which contains morphine. The argument stated in that way seems almost to answer itself. But when one looks at the Act of Parliament which we have to construe, I think it is plain that an argument of that kind cannot be maintained. The Act of Parliament provides that it shall be unlawful for any person to sell poison or to keep open shop for the retailing of dispensing of poisons, unless he holds himself out—let me put it shortly—he be a pharmaceutical chemist or a chemist and druggist within the meaning of the Act, and registered under the Act, and conforms to the regulations in the Act. Then section 2 says, "the several articles named or described in the schedule (A) shall be deemed to be poisons within the meaning of this Act," and certain other articles may afterwards be declared by the Council of the Pharmaceutical Society analogous to those mentioned in the Act. Now in the schedule to this Act is named, amongst other things, "opium, and all preparations of opium or poppies." There may be many kinds of preparation of opium or poppies, is selling that which by this Act no one can sell, without incurring a penalty, except a pharmaceutical chemist or a chemist and
Another is this—if before this Act of Parliament which we have to construe a patent of that kind had been granted, it would give to the patentee the exclusive right of making and selling the patented article, and it would have been rather hard, by this Act of Parliament, to take away from him that exclusive right under the authority of the Great Seal, and to prevent him from further making or selling, if he were not an authorised person under the Act. For these reasons I think it is plain that in section 16 the words "patent medicine" mean that which they express primâ facie, medicine the maker of which has had a special certificate of the Controller of Her Majesty's Stationery Office, that the term does not extend, and is not intended to extend, to mere proprietary medicines, or to include a medicine like this, for which the owner or maker has not obtained any patent whatever. On these grounds I think the decision of the court is perfectly right, and that this appeal fails.

Lord Justice Smith: This is a proceeding by the Pharmaceutical Society of Great Britain against a grocer, Mr. Richard Armon, and the proceedings are taken under section 15 of the Pharmacy Act of 1868, Mr. Armon—who is a grocer—having sold poisons, believed to be patent medicines, contrary to the provisions of that Act to sell poisons. The first question which arises is whether or not Mr. Armon has sold poison within the meaning of the Act, and secondly—because it seems to me the other point is secondary—whether or not this is a patent medicine within section 16 of the Act. Now, I understand this case brought for the purpose of over-ruling. If possible, three cases which have been decided heretofore, the case of Berry v. Henderson, which was decided by Mr. Justice Lush and Mr. Justice Hannon, the case of the Pharmaceutical Society v. Piper, which was decided by Mr. Justice Collins and Mr. Justice Lawrence, and also the last which was decided, which was the case of 52 Geo. III., which makes in terms a distinction between patent medicines and those medicines which are not patented. 52 Geo. III., which imposes a special duty on certain medicines which are patent medicines. "When all other medicines, made, prepared, uttered, vended, or exposed to sale by any person or persons whatsoever, wherein the person making, preparing, uttering, or exposing to sale the same, hath or claims to have any occult secret or art for the making or preparing the same, or hath or claims to have any exclusive right or title to the making or preparing the same,"—so that this shows them to be dealt with as a separate class,—"or which have at any time heretofore been, now are, or shall hereafter be prepared, uttered, vended, or exposed to sale under the authority of any Letters Patent under the Great Seal." Now, I entirely accept what Mr. Justice Collins said in the Piper case. The reason for that exemption seems to me very clear indeed. Where the medicine is, properly speaking, a patent medicine, that is to say, where the exclusive right to make or sell it has been granted to somebody under Letters Patent under the Great Seal, the condition of the patent is that a description shall be made to the Patent Office describing the whole of the ingredients and the process of manufacture. Without that no patent could be obtained—without that any patent would be void. Therefore, when people buy a patent medicine they have the means of ascertaining what ingredients are contained in that patent medicine, and that is the reason, no doubt, for the exemption.
the meaning, as I say, of the Act, and if the Act stopped there I do not see how it could be said otherwise. The Court judge and the Divisional Court were right in saying that if in the circumstances of this case, had sold a poison within the meaning of the Act, because it is found that in this Powell's balsam of anised there is a poison which is one of the poisons mentioned in the schedule. That is beyond all question. It is found at the trial that the defendant did sell a poison, and I do not think this is material for the decision we are giving to-day—but that it is in such a substantial quantity that if a child took it it would probably injure him. It had better read it: "In the case of children, however, it was stated in the evidence given on behalf of the plaintiff that if the whole contents of the bottle were taken at once by a child in ordinary health it would certainly be injurious and might be fatal, and to an infant probably fatal." (See Pharm. Journ., Ill., 769.)

Therefore, there is a poison in this bottle, which if taken by a child or an infant, would certainly or probably do damage to the taker. Now, I ask myself, has or has not this defendant sold a poison which is mentioned in that Act? I can only answer that question by saying he certainly has. Then it is said, Oh, but he did not sell the poison so, but he sold the vessel, the sellor of the vessel, is said to have been injured. I put it to the House of Commons. I will put it again. I will take chloroform, because it is a simple case. Supposing a man filled up a bottle half full of chloroform, and filled the other half with water and sold it—I put it to Mr. Moulton two or three days—do you mean to say he does not sell chloroform? Of course he does—he sells chloroform and water. He sells the less sells chloroform, and the prohibition, as I read this Act, is that he is not to sell chloroform unless he be a chemist. Therefore, it seems to me there is a direct prohibition in this Act against other than licensed persons selling poisons; the present defendant has sold a poison, and he is therefore within the meshes of this Statute. But then it is said by Mr. Moulton: "No, although you may get him into the meshes in this way, he is out of it by reason of section 16 of the Act, because section 16 provides that nothing hereinbefore—that is, in none other words, that Mr. Grey, the learned counsel, makes the case of "making or dealing in patent medicines," and he says this Powell's balsam of anised is a patent medicine. Well, the first thing one asks oneself is, where is the patent? The only answer to that is, there is no patent as all. How then do you call it a patent medicine? Mr. Grey says it is a patent medicine, and, therefore, we ought to read this section 16, which exempts patent medicines and patent medicines only, as exempting patent medicines and proprietary medicines! Well, without any authority in the Statute, I certainly should not have read section 16 in that way myself, because when the Enquiry of this Act is brought into it all the poisons mentioned in it, and secondly, all medicines made out of those poisons, exempting a few cases, the exemption must of course be read in the manner the Queen's English dictates; and when the Legislature, which has taken place before and since this Act of 1868, in which we are dealing with, is looked at, it is abundantly clear that for some express purpose the limitation and the exemption was patent medicines and only patent medicines, because if you begin with the Statute of 25 Geo. III., sec. 4, and then take the Act of 1892, Geo. III., c. 150, sec. 2, both prior to this Act of 1868, there is a distinction between a patented medicine and what I should call a proprietary medicine, that is, a medicine which is compounded of secret nostrums. When you come to the Act of 1868 the sale exception made relates to patent medicines. Then a few years afterwards—seven years—another Act is passed, in which the exception is made where the act of their own medicine, which this Powell's balsam of anised is, or is the subject of a patent in force. This clearly shows that there is a distinction to be drawn between a proprietary medicine and a patent medicine. Mr. Moulton, whose knowledge on these subjects we all know to be very large, doubted whether there was a section as a patent medicine. I can say that a specification was handed up in which it was shown that Mrs. Mary Randle, of 38, Warwick Road, did take out a patent for a medicine in 1892. So that a patent for a medicine can succeed, and when in the year 1892 the Attorney-General will pass it, and grant his fiat, all I can say is that it is proved. In my judgment, this case has been brought within the Act. Mr. Armsden cannot get out as being within the exemption in section 16, and this appeal must be dismissed.

Mr. Grey: With costs, my Lord.

Lord Justice Kay: Yes.

**ACTION AGAINST AN UNREGISTERED ASSISTANT.**

On Wednesday at the County Court of St. Helens, Lancashire, before his Honour Judge Shand, an action was brought by the Council of the Pharmaceutical Society of Great Britain against John Ernest Edington, as assistant at the World's Drug Store, 135, Westfield Street, St. Helens, to recover £5, the penalty for a breach of the Pharmacy Act, 1868. Mr. T. R. Grey, barrister, instructed by Masera, Flux, Thompson, and Flux of London, appeared on behalf of the Society, and Mr. H. L. Riley, solicitor, defended.

Mr. Grey, in opening the case, said this was an action for a penalty for the sale of poison contrary to the Pharmacy Act, 1868. The defendant was the unregistered assistant to Mr. Harrison, a registered chemist who carried on business at 135, Westfield Street, St. Helens, and on May 31 he sold a bottle of Dr. Collins' 'Bromine' chloroform that would be proved before his Honour to contain about three-quarters or more of a grain of morphine, which was a scheduled poison.

Evidence having been given to prove the sale of the chloroform and the presence of morphine in it, and the fact that his defence would be limited to the question whether or not defendant did break the law in the course of his selling the chloroform. They raised no question as to whether it was or was not a poisonous compound. He would show his Honour that there was on the premises sale, and possession of a poison which belonged to the premises belonged, and that the assistant took the bottle from the case and asked his master, who was in an inner room, if he would oblige a neighbour by letting him have it. He would thus prove that the assistant was acting under the personal superintendence of a qualified employer.

Evidence bearing out the statement of defendant's solicitor was then given, after which

His Honour said it was perfectly right that the Pharmaceutical Society should take proceedings in all cases, even of doubt, but he was not going to convict a man—for it was practically a conviction unless it was abundantly clear that the Act had been transgressed. If there was a doubt in his mind he thought he ought not to convict. It was for the Society to prove that the sale was not under Mr. Harrison's supervision, and they had not done it. It was practically a criminal case, and it was perfectly right that anybody who transgressed the Act should be punished severely, but he must be fully satisfied that they had done wrong before they were punished. He therefore gave judgment for defendant with costs.
POISONING CASES AND INQUESTS.

CHILD POISONED BY CARBOLIC ACID.

An inquest was held on Tuesday, July 10, at Clyo, near Overton, Flintshire, by Mr. E. J. Pay, coroner, concerning the death of a child, aged three and a half years, daughter of a laborer named Powell. Some carbolic acid, which had been used for disinfecting purposes, was left on the kitchen dresser, and deceased drank of it. She was given an emetic, but died about twenty minutes afterwards. The Coroner commented strongly on the carelessness of the persons responsible, and verdict of "Accidentally poisoned" was returned.—Liverpool Post.

SUICIDE BY CARBOLIC ACID.

On Wednesday, July 11, before Mr. Sampson, coroner, an inquest was held on the body of Mabel Sibyl Macallister, 16 years of age, a domestic servant who was in service in Bedford Street, Liverpool. The evidence was to the effect that the girl, who had been in good health until about five weeks back, became much depressed after the death of her father. On Monday last she was found lying in the kitchen apparently very ill. A doctor was sent for, but on his arrival the girl was dead. The medical evidence was to the effect that death was due to carbolic acid poisoning. When the girl purchased the carbolic acid she said that it was to be used in the drains. The coroner commented upon the fact that carbolic acid could so easily be purchased. Scarcely a week passed without there being an inquiry into death arising from poisoning by carbolic acid, and he trusted that there would soon be legislation with a view to making it more difficult for would-be suicides to obtain such stuff. The jury returned a verdict of "Suicide whilst temporarily insane," and expressed their agreement with the coroner's remarks as to the necessity of curtailing the facilities for obtaining poison.—Liverpool Mercury.

EXPLOSION OF A SILVERING (C) MIXTURE.

On Tuesday, July 10, Sanderson Drury, a youth of 18, who lives at 34, Dove Street, Saltaire, was nearly blinded by the explosion of a mixture of nitric acid and mercury. Drury had a brass watch-chain, and he was anxious to turn it into silver. He learnt the secret how to do this from one of the itinerant lecturers who attended his church. On Tuesday he paid a visit to a chemist and purchased a mixture of nitric acid and mercury, which was supplied to him in a bottle. He had not gone far from the shop when the bottle was blown to pieces, the glass and the acid striking Drury in the face. At first it was thought by bystanders that the youth was killed. They conveyed him to the hospital, where Dr. Foster found that there were serious injuries to the eyes and face. The usual remedies were applied, and the patient is going on as well as can be expected, though he has not yet regained his eyesight.—Yorkshire Evening Post.

SUICIDE BY ARSENIC POISONING.

On Wednesday, July 11, John Duncan, 62, shoemaker, living in Dallfield Walk, Dundee, committed suicide by taking white arsenic. Duncan was found lying on his bed, and on being asked whether he was unwell he said, "I have taken poison." Later, he became unconscious and frothed at the mouth. Medical aid was at once summoned, and Dr. Young, who attended, ordered Duncan's removal to the Infirmary. On searching the house Mrs. Duncan discovered in the fireplace a piece of white paper on which was marked "White Poison." Since the Infirmary every means was taken to restore Duncan, but he died about ten minutes after admission, never having regained consciousness. Death was due to swallowing a large quantity of white arsenic. It is believed that Duncan had purchased the poison from a drug store, stating that it was for use in his occupation.—Dundee Advertiser.

Reviews and Notices of Books.

The nature and methods of absorption, symbiosis, action of plants on the soil, transpiration, protective arrangements of the epidermis, and kindred subjects are dealt with in this part of the work. The beautiful coloured plate represents tropical epiphytes in Ceylon—Saccalobium guttatum, Dendrobiun nobilis, and Phajus mallichii.

This little book deals with the choice of apparatus, description of lenses, and the various operations involved in preparing and printing from photographic negatives. In addition, there are chapters on chemicals in common use in the art, detective cameras, stereoscopic photography, lantern pictures, enlargements, photo-micrographs, weights and measures, and photo-mechanical printing processes. No pretence is made to give exhaustive descriptions of the various processes referred to, but in the brief space available enough is said to enable a beginner to form a fair idea of the scope of photography, and to readily overcome the elementary difficulties that lie in his path.

Notes and Queries.

BLAUD'S PILLS.

A simplified formula for these pills, said to yield a more permanent product than the original, is given by J. W. England, as follows:—"Potassium carbonate, one-third grain, potassium sulphate, two grains, and mass of iron carbonate, three grains, in each pill. Little or no excipient is required. The pills flatten somewhat on keeping, and are best dispensed in gelatin capsules. They are small in size, and do not become hard and reddish-brown on fracture, as do those made by the old formula" (Am. Journ. Pharm.). The "mass of ferrous carbonate," U.S.P., is prepared by dissolving ferrous sulphate 100 Gm., in boiling distilled water 200 C.c., and adding syrup, 20 C.c. (Syrupus, U.S.P., contains 500 Gm. of sugar in 1000 C.c.). Sodium carbonate 100 Gm. is also dissolved in boiling distilled water, 200 C.c., and, when both solutions are cold, the first is gradually added to the second, in a bottle of about 500 C.c. capacity. When gas no longer escapes, distilled water is added to fill the bottle, which is then corked and set aside for the ferrous carbonate to deposit. After decantation, the precipitate is thoroughly washed with a mixture of syrup (1 vol.) and distilled water (19 vols.); then mixed with clarified honey, 88 Gm., and sugar, 25 Gm.; and finally evaporated on a water-bath until reduced to 100 Gm.
OINTMENT OF AMMONIATED MERCURY.

This ointment J. W. England prefers to make by finely powdering the ammoniated mercury, then beating it into a smooth paste with one-fourth its weight of glycerin, and preparing the ointment from the mixture as required. Entire freedom from "grit" is said to be obtained. Glycerin is also recommended for rendering varitrine smooth or making extract of belladonna soft, prior to making ointments from them (Am. Journ. Pharm.).

MEDICATED WATERS.

In the new U. S. P. these are directed to be made by using precipitated calcium phosphate as a distributing medium for the essential oils. J. W. England urges the advisability of invariably adding the whole of the water to be used to the mixed oil and phosphate, before filtering, as a stronger solution is thus obtained. If hot, boiled water be used a further advantage is obtained, for, in addition to obtaining a maximum solution of the oil, there is an increased permanency of the water. The loss of oil by volatilisation, in this case, is said to be more apparent than real, being insignificant in comparison with the greatly increased amount brought into solution (Am. Journ. Pharm.).

CINERARIA MARITIMA.

"Can you give me any information regarding the therapeutics of Cineraria maritima and its synonyms?"

—DAVID GORDON.

Cineraria maritima was recommended for soft leucitic cataract by Dr. R. Mercer, of the Fort of Spain, Trinidad. His letter, forwarded by the Director of Ken Gardens, was published in the Pharm. Journ. (13), xxi., p. 985. There are two plants which have borne the above name; the one which is apparently intended being the Senecio cineraria of Linnaeus. The other is the Senecio gibbosus of De Candolle. The latter differs from Linnaeus' plant chiefly in the nearly sessile leaves and glabrous involucre. It is found in Sicily and Calabria; Senecio cineraria occurs generally on the shores of the Mediterranean, from Spai to Greece and Egypt.

TERRINE'S EMULSIONS.

Torrance should be etrified, according to C. B. Lowe, by the addition of a drachm of powdered gum arabic for each fluid drachm. The emulsion is difficult to make, on account of the great tendency of the terrine to separate, and the method recommended is, first, to carefully mix the gum with the water, and then slowly and cautiously add the terrine (Am. Journ. Pharm.).

FORMALIN IN PHOTOGRAPHY.

On half imprinting a finished negative in 40 per cent. formalin solution, Dr. F. D. Steel found that the portion immersed became slightly opalescent, but cleared perfectly after being a short time in cold water. The portion of the film so acted upon did not swell in the water to the same extent as the other half. Subsequent experiments with soft gelatin in sheets showed that, after treatment with formalin, it became insoluble in boiling water, while remaining transparent. It was also noticed, however, that on softening the gelatin in cold water before immersing in the formalin solution it remained partially soluble in boiling water (Photography).

CORRESPONDENCE.

NOTES AND QUERIES.

Sir,—I sincerely hope that your readers will not lose sight of the fact that the President of the North British Branch of the Pharmaceutical Society Mr. Lunan gave notice that he intended to move a resolution recommending the Council to consider the desirability of enlarging the Journal, and expressed an opinion that it could be done without being popular and valuable by the introduction of dispensing memoranda and notes and queries than it is at present as a simple record of transactions. It may have been by a consideration, but in the very number in which the report of the above meeting appeared, a column of "Notes and Queries" was included for, I believe, the first time in recent years, a departe promiessing to give excellent results, judging by the forecasts we have had. That there are many interesting and knotty points arising daily at dispensing counters all over the kingdom which it would be most profitable to your readers to have thrashed out in the Journal no one will for a moment doubt; but there is always a large amount of diffidence to be overcome before the persons under whose notice these difficulties fall can be persuaded to mention them at meetings of a pharmaceutical character or even to write for information. No doubt this is due to a vague fear that their query may be considered as one of those things which that encyclopaedia of more or less useful knowledge "every schoolboy is supposed to know" and that they may be quaintly "sat upon" for their pains. Such a fear need not trouble them any longer when a column is reserved for their use, and it only remains for them to make such use of it as will render it as valuable to your readers as I find the column headed "The Month," which I consider of itself well worth the annual subscription.

Liverpool.

H. WYATT, JUN.

PROTECTING THE TITLE.

Sir,—Referring to Mr. Ellinor's letter in your issue of June 30, I am informed that the Pharmaceutical Council refuses to move in the matter because eminent counsel are of opinion that the attempt would not be successful. I do not think that is satisfactory. It is the duty of the Council to remove all doubt about the title, as it was its duty to remove doubts about poisonous proprietary medicines. I am sorry that it is not possible this being done until outside pressure was brought to bear?

3, Market Place, Derby.

JOHN A. COPE.

EDUCATION AND EXAMINATION.

Sir,—The topic of "examinations" has again cropped up. A mother went to see how her son was getting on at school, and the master told her "Pretty well, but he wants a capacity." "Oh! we will soon get him one; how much is it?" I am afraid that the school has not the deal to answer for if a boy does not get on, for generally if the school fees are paid, and he is not guilty of misconduct, not much attention is given to his want of success. In every school there are pupils who succeed very well, some pretty well, and others not at all. In one of my addresses to the North Kensington Chemists' Association, I pointed out that chemists do not learn the lessons they ought from the subjects they have studied. Botany teaches us unity and order, and chemistry-purity and compatibility. Now, as we know that all boys have not a proper capacity, and chemists buy "elect" drugs, so they should have apprentices "elect," not "sorts," for it is worse than useless and even cruel to bring unsuitable candidates into pharmacy. Therefore the sooner the mistake is found out the better, and more so as pharmacy is becoming more complex every day. The Preliminary must be strengthened and passed before apprenticeship, and the proper curriculum should be. This is what is generally conceded, and it is time it was so established, and only those taken who have passed the examination. No one ought to (I was going to say be allowed) take apprenticeships for cheap labour. They are to be able and this being done the nature of the duties must be entirely changed, for while I would not object to a very short spell of the "rudiments," duties devolving on the errand boy should be

SUGAR IN URINE.

Sir,—That Sir George Johnson has rendered a signal service to medicine by his very able paper, "On Some Common Sources of Error in Testing for Sugar in Urine," no one who has ever engaged in its clinical examination can gainsay, and pharmacists should be grateful to you for giving such a bold advertisement in your pages. It is not altogether satisfactory that medical men deep in the mysteries of a case, and sometimes fogged by obscure symptoms, should play the part of animal chemists too—in fact, it seems hardly fair. Sir George Johnson's paper, if published thirty years ago, would have enlightened many, and saved much hardship and suffering, but without more light it is rather heroic for a chemist to tell a medical man that urine contains no sugar, and he could only do it by regretting the copper test, and carefully using the test, especially beginning with Moore's liquor potasse test. I was immensely amused at Sir George Johnson's lead fallacy in that otherwise faithful preliminary test, the doctor must have been rather weak in shades of colours. It is indeed an anxious and responsible task, I know of none more so, except making preparations or dispensing prescriptions, the principles governing this work ought to be explained, and proper time given him to study botany, chemistry, and materia medica, with encouragement, may, more, insistence that he should do so, not after the shop is shut, when he is tired and fagged out, but as part of the day's work, and with reasonable time. We have reason to believe the lad will not learn, he hates all trouble, and often passes his time without any study. There is a general idea that an apprentice should select one of the "provincial centres" with a college. This, of course, is the best, but the pupil ought to be able to ground their apprenticeships in all subjects, often having more room and leisure, and in return find it a "profitable extra." I quite agree with the late Henry Doyne, the chemist ought to get a good fee for his trouble, and it would ensure his pupil having the necessary capital to pay for his education, without calling on the Pharmaceutical Society to clothe, educate, and examine him for nothing, besides ensuring his success in business afterwards.

HENRY LONI.

Answers to Correspondents, etc.

Robert Crofts.—Both are apparently garden escapes of cultivated forms of Herba sparsa. William Kirby.—Your criticism of Baron von Müller's remarks will be communicated to him.

Obituary.

Notice has been received of the death of the following:-

On June 6, Stephen Massy, Chemist and Druggist, Fenton, Staffs. (Aged 62.)

On June 16, Frederick W. Irving, Chemist and Druggist, late Gosberton. (Aged 35.)

On June 19, Henry A. Williamson, Chemist and Druggist, of Scarborough. (Aged 57.)

On June 27, Charles J. Boorman, Chemist and Druggist, Malvern Link. (Aged 60.)

On July 1, John Dale, Chemist and Druggist, of Macclesfield. (Aged 54.)

On July 8, Joseph Ruston, Chemist and Druggist, Manchester. (Aged 46.)

Diary of the Week.

Tuesday, July 24.

Quoted Microscopical Club.

Excursion to Norbiton for Richmond Park, returning to Richmond. To meet at Waterloo (south station.)

COMMUNICATIONS, LETTERS, etc., received from Messrs. Allen, Clarke, Clower, Cocks, Hill, Hyslop, Ince, Kirby, Mathews, Mee, Moline, Naylor, Reynolds, Sichs.
THE MONTH.

In cases where it is not essential that the determination of albumin in urine should be very exact, Rösler recommends a volumetric method which can be carried out very readily, and gives results that are comparable. Into a test tube containing a mixture of 5 c.c. of acetic acid and two or three drops of potassium ferricyanide solution (1 to 10), the urine to be tested is poured through a funnel, so as to form a layer on the surface. When albumin is present a white zone is formed, which is proportionate in thickness to the amount of albumin, and the indication thus afforded in from ten to thirty minutes may be taken as a measure of the relative proportion of albumin in the urine (Apotheker Zeitung, ix., 563).

Test for Chlorides. Villiers and Fayolle find that a still more delicate test than the one they recently proposed for chlorides (Ph. J., liii., 1065) consists in alkalizing ortho-bromide for the anilide previously recommended. A sharp reaction is then obtained with less than 1/10 Mgm. of chloride, a fine blue coloration resulting, and changing to reddish-violet on the application of heat or cold. The reaction is, however, not sharply defined from that given by bromides under similar conditions, unless aniline be also present. The following formula is therefore given for the reagent: —Colourless, saturated, aqueous solution of aniline, 100 C.c.; saturated, aqueous solution of ortho-bromide, 3 c.c.; glacial acetic acid, 30 c.c. On using this reagent, any bromides and iodides present are acted upon by the aniline, forming white or colourless compounds, and the action of the ortho-bromide on the chlorides present is not observed (Comp. rend., cxviii., 1413).

Crystallised Aluminium Carbide. H. Moissen has prepared, by the aid of his electric furnace, a crystallised compound of carbon and aluminium, represented by the formula C3Al4. The compound occurs in the form of fine, transparent, yellow crystals, containing a diameter of 5 Mm. in 5 Mm. in some instances. This density is 2.36, and the compound requires the highest temperature of the electric arc for decomposition. It possesses very marked reducing properties, and slowly decomposes water at the ordinary temperature, methane, CH4, being evolved (Comp. rend., cxx., 16).

Picro and Picrosol. Picrose is the name applied to one of several new glucosides, obtained by M. Tarret from the leaves of Pivaux (Pisum cyminum). It is crystallised from water into its formyl 0, C3H6O2, CO. Both this and the anhydro-compound form silky prismatic needles, with a bitter taste. They are soluble in 1 part of boiling water, 50 parts of water at 15°, 20 of alcohol at 70° and 88 at 90°, 534 of absolute alcohol at 15° and 33 at boiling point, whilst acetic ether dissolves 1 part in 123 at 15°. The glucoside in insoluble in ether and chloroform, is dextrorotary, and when anhydrous melts at 194°. Under the influence of emulsion, or of dilute acids, it is split up into glucose and "picrosol," C8H8O2. This latter melts at 106°, and is soluble in 100 parts of water at 15°, and in 14 parts at 100° (Comp. rend., xix., 80).

Determinations of Antipyrine. M. F. Schlack bases a colorimetric method of determining antipyrine on the colour reaction that occurs when sodium nitrite is added to an acidified, dilute solution of the base. The blue-green colour produced is said to be still perceptible in dilutions of 1 in 20,000, whilst in more concentrated solutions a crystallizing precipitate of the same colour is formed. It was found that a standard solution, stable for twelve to twenty-four hours, can be made by dissolving antipyrine, 0.02 Gm., in water, 25 C.c., adding 1 per cent. sulphuric acid, 1/6 C.c., and 1 per cent. sodium nitrite solution, 0.8 C.c., then diluting to 100 C.c. When preparing a solution of an unknown amount for comparison with the standard, a few preliminary trials should be made to determine the amounts of reagents required to fully develop the colour, without being in excess, and to avoid precipitation the solution must not be more concentrated than 1 in 500. When properly prepared, the solution can be diluted until the colour corresponds exactly with that of the standard, and the amount of antipyrine present is then readily determined by calculation. The reagents employed do not react with other substances, except pyrazol compounds, which are not of frequent occurrence (Am. Journ. Pharm., ixvi., 322).

Iodides. G. B. Frankforter describes these compounds. The blue iodide, (C8H7N2O3)3I4+S2H5O, is formed when a solution of iodine in aqueous solution of iodine. Also, by treating crystals of narsenic direct with iodine, indigo-blue crystals are formed, which retain the same crystalline form as the narsenic. On heating these crystals they change from fine long prismatic needles to short irregular ones. The blue crystals are slightly soluble in water, soluble with difficulty in alcohol quite insoluble in ether or chloroform, and melt at 175°-177°. The red iodide, (C8H7N2O3)3I, is formed by treating narsenic with an alcoholic solution of iodine, and the green-blue crystals obtained by reducing and losing its crystalline form on standing in the air or gently heating. It melts at 181°, and is insoluble in water, alcohol, or ether. Both iodides are transformed into narsenic by carefully neutralising with sodium hydroxide. In the presence of an alkali no iodide is formed from narsenic (Journ. Am. Chem. Soc., xvi., 361).

Micro-chemistry of Albuminoïds. Dr. De Wevre concludes an exhaustive communication on the methods employed in micro-chemical researches on the albuminoïds, by stating that these compounds cannot be localised by any single reagent, a combination being required always. He recommends that sections should be boiled first in water, and then in absolute alcohol, before adding reagents. The best of these for the purpose, arranged in the order of their sensibility, are iodised potassium iodide or an aqueous solution of eosine; Millon's reagent; picric, xanthoprotein, or phosphorylobiic acid, and Guezda's reaction; Piotrowski's biuret reaction; Reichel and Mikosch's reaction. If all these reagents act, after treatment of the sections with boiling water and alcohol, it is safe to conclude that the proteid substances are present. In Guezda's a reaction a concentrated solution of nickel sulphate saturated with ammonia turns yellow or blue with
proteid matters, the blue changing to orange yellow on adding caustic potash. Reichel and Mikosch's method is to add to the substance under examination about twenty drops of an alcohol solution of bismale-
dehyde, followed by an excess of sulphuric acid diluted with its own bulk of water, and containing traces of ferric sulphate. An intense blue coloration is thus imparted to albuminoids. Absolute alcohol is recommended as the best coagulating medium; and the xanthoprotein reaction is said to be very good for sieve tubes, in place of osin. It is stated also that the albuminoid reactions of sieve tubes are not always very intense, and that a large quantity of proteid substances occurs in the growing points of roots and in the laticiferous tubes of various plants, notably Carica papaya (Journ de Pharm. d' Anvers, i., 209).

Yeast Cells and Fermentation.

A. J. Brown points out that the usually accepted view, originated by Pasteur, as to the cause of the ex-
bition of fermentative functions by yeast cells is that it is a starvation phenomenon, brought about by lack of free oxygen during the life of the cells in a fermentable liquid. Briefly this may be defined as "life without air." Pasteur's experiments are reviewed by Brown in conjunction with the results of some of his own, which contra-
dict Pasteur's theory, and he concludes that there is no prima facie reason why the yeast cells should not exercise their fermentative functions inde-
pendently of their environment, so far as the presence or absence of free oxygen is concerned, and that there is nothing in Pasteur's experiments to contradict this (Proc. Chem. Soc., 141, 159).

J. Effront has previously shown (Ph. J., liii, 441) that beer yeasts, and
Antiseptics and Antiseptic action of fluorine, manifest a change in the chemical products of their activity. He has now demonstrated that similar modifications can be produced, in the same way, in the results of the fermentative processes induced by the lactic, butyric, and acetous fermentation, when two per cent of fluorine is being formed in addition to those usually obtained. As in the case of yeast, the fermentative power is also augmented, though the increase of the fermenters is checked (Comp. rend., cxxix., 169).

American Power and Kleber have deter-
mined the constituents of this oil, which they summarise as follows—:

- Aetatelehyde, OH—COH ;
- Valeraldehyde, (OH)2OH—CH2—COH; acetic acid,
- OH—COOH ;
- Nornevaldehyde, (CH2)3OH—COOH ;
- Pinene (inactive) ;
- C15H18; phellandrene, C12H20; limonene, C10H16;
- cineole, C14H22 ;
- Menthone, C10H18 ;
- Menthol, C10H19—OH ;
- Menthyl acetate, C10H18—CH3 ;
- Menthyl iso-valerate, C10H18—CH2—CH3 ;
- Menthyl ester of an acid, C10H18—C10H18—CH2—O; a lactone, C10H18—O; and cadinene, C1sH34.

Though the composition of the oil is so exceedingly complex, it may be assumed that most of the constituent compounds are in genetic connection with each other, and that the processes by which they are produced in the plant are relatively simple. The specific gravity of peppermint oil generally is stated as varying between 0·905 and 0·916, and its optical rotation in a 100 Mm. tube lies between −25° and −35°. The amount of menthol in the form of esters varies between 3·45 and 14·12 per cent., and the amount of free menthol from 24·2 to 75·7 per cent. The American product is less rich in menthol than Micham, Saxon, or Japanese oil, the last being richest of all (Frisch's Bureau of Circ., No. 3).

Areae and Oateshe.

The areas of the fibrous part of the araeum leaves, and produces successively three or four in florescences, which exhibit as many stages of development. The pericarp of the unripe fruit is green, that of the ripe yellowish-red; it encloses the seed, which lies nearer the apex than the base. The pericarp is differentiated into three layers, the outer of which is thin. The middle layer consists principally of fibres, and is permeated by fibro-
vascular bundles, whilst the inner layer forms a thin but firm sheath enclosing the seed; the fruit is therefore to be regarded as a drupe. The fibres of the middle layer are set of bundles of scleran-
ymatous fibres, and either accompany the fibrovascular bundles or take a separate course; they frequently anastomose, and thus produce the fibrous toughness of the pericarp. These bundles are accompanied by stone-cells, the number of which increases until the hard inner layer is formed. The pericarp also contains raphides in bundles, and cells filled with a red secretion. The seed is bluntly conical, and possesses on the flat side a small warty excrescence, the micropyle, which in drying forms a little depression. The tests are closely applied to the carillaginous endosperm. The outer layers are mostly lignified and easily removed; in the ripe seed they are often absent. The inner layers are brown and contain tannin. The cell walls in the endosperm are much thickened, and have few but large areolated pores. The ovule has two integuments; the formation of the rumina-
tion commences in the funicular region by the de-
velopment of masses of tissue in the form of horse-shoes opposite the fibrovascular bundles. Smaller masses are more posteriorly situated at the sites of the fibrovascular bundles. The brown lines seen on a section of the seed consist of cells con-
taining tannin. They are arranged in a layer two or three cells wide immediately under the epidermis, and accompany the fibrovascular bundles into the ruminations. The principal alkal-
oid, arecoline, is not deposited in the endosperm, but in the ruminations; this localisation of alkal-
oid and tannin is regarded by the author as a pro-
tection to the plant (Dissertation, Marburg, 1894).

The exact botanical source of the

Strophanthus seeds that have been known in commerce under this name has never been accurately determined. Dr. Franchet suggested a few months ago that they were probably derived from the plant known as Strophanthus gratus, but as the fruits of the plant were not well known, the point remained doubtful. He has now received fruits from a cultivated plant of this species, which enable him to confirm without doubt his previous opinion, and further show that, as suggested by Professor Baillon some years ago, the genus Strophanthus must be sunk under Strophanthus as a section or sub-genus. Conse-
quently Strophanthus gratus, Franch., will be the name in future for the plant yielding the glabrous Strophanthus seeds of commerce. Dr. Franchet believes, however, that some of this seed may be
yielded by the closely allied species, *S. Tholloni*, which has the same geographical distribution, viz., from the Equator to 6° S. lat. (Journ. de Botan., viii., 201).

Wood Cressotia. Wood Cressotia.  
find that beechwood cressotio is richer in guaiacol and has a greater density than that from the wood of the oak. It also contains less monovalent phenols and is, consequently, less caustic, the causticity of cressotio being essentially due to the monovalent phenols. Cressotio is generally regarded as consisting of a mixture of guaiacol, together with cressotio, and a small proportion of monovalent phenols. The composition of beechwood cressotio, passing over from 20° to 210°, is given, however, as follows:—

Monovalent phenols, 39 per cent.; guaiacol, 26.48; cressotio and its homologues, 32.14; losses, 2.38. Oakwood cressotio, under similar conditions, yielded—monovalent phenols, 55 per cent.; guaiacol, 14; cressotio and its homologues, 31 (Comp. rend., crxxix., 166).

They were collected by L. G. Browne, who states that the natives employ the plant with good effect in cases of diarrhoea. Apparently, the fruits are from a small-fruited species of *Zizyphus*, near *Z. cuneifolia*. All the species of this genus are probably astrigent (Botanical Record, xvi., 135).

Respiration of Leaves. Respiration of Leaves.  
Maquenne has endeavoured to throw fresh light on this subject by comparing the respiration of different kinds of leaves, both in the normal state and after previously remaining for some hours in a vacuum. He wished to ascertain, if possible, whether the evolution of carbon dioxide by plants is due, as in fermentation, to the splitting up of some compound previously oxidised; or if it is the result of the combustion, pure and simple, of some principle continuously elaborated by the plant, that oxidises on exposure to air. Maquenne favoured the second of these hypotheses, according to which the living cell constantly secretes a combustible substance which, by simple combustion with air, gives off carbon dioxide. By checking the action of the oxygen this product would accumulate, so that, on the plant being again brought in contact with the air, respiration would be increased accordingly. To avoid the introduction of error due to differences in the specimens experimented with, the leaves compared were, in each case, taken from the same plant, besides being of the same weight and as nearly as possible of the same age. As a result of the experiments it was found that, in all cases where the plant was able to resist the effects of the vacuum, without undergoing appreciable alteration, it afterwards disengaged a much larger quantity of carbon dioxide than it would have done had it simply been left exposed to the air. Figures based on actual experiment with a number of leaves appear to go far towards proving the truth of the hypothesis (Comp. rend., crxxix., 100).

Secretion of Resins. Secretion of Resins.  
W. Sieck contributes the results of work undertaken with the object of throwing some light upon the formation of the so-called "schizol-syzigous" secretion-ducts, especially in Rutaceae and Diplocarpaceae. Amorosana have long been at variance concerning the origin and growth of these ducts in rutaceous plants, some insisting on their purely schizogenous, others on their purely syzigous origin and development, whilst others again have maintained that the origin is schizogenous, but the development syzigous. In Rutaceae, W. Sieck finds a single cell divides, and the young cells thus produced separate schizogenously. The secretion (oil) is formed in the cell-wall bordering the cavity, and by its pressure bursts the thin muclaginous membrane which retains it in the wall; it is then discharged into the cavity. The inner membrane, unable to withstand the extra pressure put upon it, also bursts, and the cavity thus increases syzigously. Simultaneously, the middle lamella is converted into mucilage, and the cell breaks up. In *Anacardium occidentale* numerous cells which had become isolated in this manner were found free in the resinous secretion (Archiv., crxxii., 307).

H. Vincent, described, at the last meeting of the Société de Biologie, a staining process applied to the blood, cable to every variety of organism occurring in the blood. It is based upon the principle that colouring matters fix themselves to the hemoglobin and not to the protoplasms. If, therefore, the hemoglobin be removed, and the stain then applied, the blood globules remain uncoloured, whilst the microbese are coloured and stand out with great clearness. The blood is spread in a thin layer and slowly dried, after which it is treated with the following solution, which dissolves out the hemoglobin:—Aquous 5 per cent. carbolic solution, 8 C.c.; saturated solution of sodium oxalate, 30 C.C. Glycerin, 30 C.C. Filter before use. From half a minute to two minutes suffices for this fluid to act, and it is then drained off, the blood washed with distilled water, and staining effected with carbolised methyl blue, to which from 1 to 20 per cent. of aquous methyl violet solution has been added (Medical Press, crxxi., 10).

Hemming draws attention to the danger of sublimating sweetweat and sublimating pastilles, as being a probable source of danger, and mentions a case which he has called upon to examine an article supposed to be a sweetweat, which turned out to consist of mercuric chloride and common salt.

C. B. Lowe has found pokroot Belladonna (Phyllolaca decandra, L.) mixed with Rost. belladonna root, but it is easily distinguished from the latter, he remarks, by having a yellowish brown-grey cork layer, marked by transversely elongated warts of a lighter colour, whereas the cork layer of belladonna root is of a very light brown grey colour. Belladonna also, in transverse section, shows a fine black cambric ring, and the radially arranged wood wedges are light yellow. In pokroot, on the other hand, the woody tissue is whitish, and shows a distinctly concenetric arrangement (Am. Journ. Pharm., liv., 353). Pokroot, as met with in this country, is not likely to be confounded with belladonna, since it is of much greater diameter. Belladonna root, too, which shows distinct wood wedges, is here regarded as old and too woody for use, and, indeed, is not in accordance with the description in the U.S. Pharmacopoeia.
"THE DRUGGIST'S FIGHT FOR PRIVILEGE."

Under this heading, the Whitehall Review of Saturday last publishes the following pertinent article on a matter of great moment to chemists and druggists at the present time:

In all ages, and in most parts of the world, there have always been two classes of humanity more or less at war with each other. The first represents those who, through the labour of themselves or their forefathers, possess something of current value; the other is composed of men not so fortunate. An opposition of interests, resulting from these facts, is productive of an everlasting contention, which exhibits its resources in, and by, methods as multitudinous as the numberless exigencies accruing to a state of civilisation. This postulate has been illustrated by a recent case, thrice fought out, with identical results, in our courts of law. We have all heard of Derby; but to admit a rooted knowledge of the existence of an individual named Armoor of that place is quite another matter. Yet he lives, he sells, he fights. We have heard no hint of a pugilistic encounter, and yet the pother is all around a box of pills. Why should a grocer not sell pills? Some people may find it hard to swallow the bolus, but the Local Court, the Divisional Court, and the Court of Appeal all say that a patent pill, if possessing a poisonous potion, should only be procured from a pharmacist. This is the momentous question just decided for the third time of asking. Thus the chemists, for once, have scored a conquest.

Now, apart from all facetious surroundings and considerations, there is a great principle of government connected with this contest. It reopens the problem of class privilege. In the good old days, when trade guilds held paramount sway in their several restricted spheres, it would have been practically impossible for a bricklayer to become a tailor. And even now, amongst a very different part of the community, such an artist of the humorous as Toole is not considered capable of assuming the tactical responsibilities of an Evelyn Wood. Through the decades of the past a judicious division of labour has developed the majestic resources of our glorious empire. But it may be that the growth of freedom has enfeebled the roots of freedom, from which prosperity evolves. And this aphorism seems to be becoming manifest amongst those persons who are sometimes contemptuously called middlemen—such distributors of the necessities of life as chemists and grocers.

Now, a chemist is a more or less educated man who has passed through the ordeal of an examination, and obtained the licence of the State to deal in physic and deadly drugs. With him knowledge and business are co-ordinate factors of existence. He studies for the purposes of business, and he subjugates business to the end of acquiring a better knowledge of his semi-profession. But a grocer is usually quite a different kind of individual. He orders sugar, by the ton, and mixes tea by rule, and the one simple problem with which he continually grapples is how to multiply, or, at any rate, preserve intact, the capital with which he commenced business. Such a man is not qualified to vend poisons and medicine—not even patent physic. Yet, assuming that the grocer is competent to sell a tin of lozenges, not knowing or caring of what deleterious substances they may be composed, it is not equity to transfer easy business from the chemist to the grocer, and leave the former to exist as best he may upon the diminished scope of mutilated privilege.

It may appear trivial to maintain that a grocer is not likely to be sufficient master of a chemist's special knowledge to become his legalised competitor, but it is not customary in time of war for generals and admirals to exchange duties. It is very questionable if the transference of a part of the liquor traffic from publicans to grocers has been a beneficial proceeding, and it seems equally undesirable to allow "universal providers" to dispense mechanically, by weight or measure, any medicinal substance, whether patented or not, of the chemical qualities of which they are almost necessarily ignorant.

So far, then, as the particular matter in question is concerned, it appears to be in accordance with the fitness of things that chemists should be allowed to appropriate a monopoly in the sale of drugs. But this reflection suggests a consideration of one of the fundamentals of political economy. While the liberty of the subject necessitates a scope for the exercise of individualism, the protection of the subject requires a socialistic restriction of desultory action—we mean to say that there is, was, and will be, a certain socialism of classes, by which lawyers, doctors, plumbers, and most other trades and professions, combine for the maintenance of their particular privileges, to the exclusion of all other men, to a very great extent, from the advantages of their various combinations. This conservative socialism is good, because it has a tendency to develop efficiency.

It may be hard for a man who has not been articulated or apprenticed to find it difficult to make headway in life, but a "Jack-of-all-trades," without a thorough knowledge of anything in particular, can never be a producer of the best work, whether mechanical or professional. There are indications on all hands, notwithstanding the prevalence of Liberal and Radical ideas, that greater value will be given to the almost obsolete plan of apprenticeship and the motto of "every man to his trade." Such a reverting to old-fashioned methods is desirable, as being calculated to promote that stability of government which results from a consciousness in men that the State is protecting their individual privileges and well earned prosperity.

ANTIPYRINE AND SPIRIT OF NITROUS Ether.

Since the reaction between these preparations, and the consequent formation of nitroso-antipyrine, only takes place in the presence of free nitrous acid, M. F. Sohassk suggests that the neutralisation of the spirit when acid, with potassium bicarbonate, will prevent the difficulty arising from its incompatibility with antipyrine (Am. Journ. Pharm.)
THE NOOTUM TRADE.

There seems to be something in human nature that makes it impossible to stop the ever-increasing irregular traffic in medicinal remedies. The law leaves the medical profession and the pharmaceutical body to look after their own interests, and seldom interferes with the great interest which the public has in the matter, except in the form of a coroner's inquest. The wholesale robbery of ignorant persons that goes on through the agency of advertisements has been so often referred to in these columns that it need not now be described in detail, but in some cases of really potent remedies it may be asked whether some practical steps should not be taken to check their sale direct to consumers without the intervention of the qualified medical man to prescribe and the qualified chemist to dispense. One "world-famed" preparation, which owes its power to iodide of potassium, is recommended in advertisements adorned by testimonials from persons who, surely, little dream that their testimony amounts to a confession of their having suffered from syphilis. Another preparation, containing strychnine, is gravely recommended for difficult or painful parturition, amongst a host of other ills, and its proprietors, assuming the rôle of the physician, give rules for the general management of health, which include the sagacious advice that those who suffer from rickets should take exercise on horseback. We need not refer at length to the host of American advertisements which load every medical man's waste-paper basket. A large proportion of the preparations they relate to are said to give vigour to the sexual organs. We may take one example to show their impertinence. This is the "Od Quarterly, a free journal of practical therapeutics for physicians only." This precious publication, which puffs a nostrum for all disorders of the sexual organs, from stricture of the urethra to "pre-senility," is composed of testimonials from medical men unknown to fame, interlarded with pithy aphorisms for the guidance of medical practitioners, who, in their ingratitude, consign the "Quarterly" unread to their waste-paper basket. Some of these aphorisms may be quoted: "When you are in doubt as to the diagnosis, examine the urine." "Cocaine prevents suppuration in small-pox." "Citric acid is said to be a prompt remedy to stop nose-bleeding. A solution injected into the nostrils." "Excessive vomiting is easily controlled by administering one-half to one drop of oil of cloves in a little water." "Muriate of ammonium in full doses will overcome the immediate effects of drunkenness." We may judge how much the medical profession lose by not reading this paper, but they are at any rate spared the bitter regret of having spent years of study and large sums of money in learning their profession.

Indeed, with such numbers of proprietary remedies manufactured at home and abroad there appears to be no longer any call for the art of prescribing or the art of dispensing. The pharmaceutical chemist may save time and trouble, and escape the task of dispensing and of learning to dispense. He need not be more than a salesman, and might well combine his occupation with that of a grocer or an oilman. Indeed, we may ask what need there is of him at all? when simple girls as well as he can hand over the proprietary medicine counter all that the doctor need prescribe, all that the patient need consume. Such facile distribution as this would economically replace that old-world person, the pharmaceutical chemist, and largely does so, in our metropolitan "universal-provider" emporia. The chemist gone, why keep the doctor? As education increases, board school physiology, backed up by the medical column of the weekly newspaper, would help the populace to choose their remedies. Thus a perusal of the advertisement referred to above would lead the woman labouring to excess of child to send straightway for a bottle of the syrup and dismiss the accoucheur. Though obtaining money by false pretences is a penal offence, money is daily obtained in golden piles by means of lying quack advertisements, and yet the law is difficult to apply. Expensive shops for the sale of electrical appliances are not kept up by philanthropists, as we have lately been made aware. The eyes of the public are opened now and again, but they quickly close, so that it becomes worth while to expose advertisements, such as "The new scientific `Aural Battery' (patented) cures deafness, head noises, discharges, etc., no matter of how long standing or from what cause arising, etc. Artificial ear-drums superseded." The more common-sense is outraged by the effrontery of the quack the greater the confidence of his prey. "Cancer cured without the knife" is the cry of the surgical quack.
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS. (July 30, 1864)

The victim, in hypnotic terror of the knife, bears patiently the torture of arsenical caustics without a murmur, and is made to forget that, while the knife would not be felt, the prolonged torture of the cauterisation will be all in vain.

Before attempting to answer the question whether it would not be well to do away with all irregular prescribings, operating and dispensing, we must reflect that a certain amount of reactionary spirit is healthful to all institutions, even to that of medicine. There is also another side to the question. We must take cognizance of the vast amount of pleasure many matrons derive from the study of the "Homeopathic Look-within-for-Everything," as applied to the occupants of the homestead, from the children to the cows. Perhaps some guidance may be gained by inquiring what course medical men pursue when they fall ill themselves. Do they fly to the cure-all quack? Do they not rather seek the aid of one of their colleagues, and obey him—somewhat peevishly at times, perhaps. This may lead us to an answer. Moreover, we are told there is plenty of reactionary spirit intrinsic in the medical profession itself to keep it healthy. No regular practitioner regards medical science as complete and perfect, but all strive after perfection. They forget, perhaps, the pure HAHNMANNIAN, who says all ills, from cancer to toothache—everything—can be cured by pale phantoms of drugs. But they have heard of ultra-homeopaths crying loudly for the knife to be used on themselves, while their patients in similar straits are dosed with much daily profit—to whom need not be said. And if it were possible to cut off unqualified and irregular practitioners of physic and pharmacy root and branch, should they be compelled to cease from troubling? Have they done no good? That is a difficult question to answer. The homeopaths have shown that many ailments are recovered from by nature, and without even their mystic minium-millionths. But the "reverend" consumption-curing quack? Must he be held sacred, because his puffs appear in religious weeklies? Is he to be allowed to sweep to his pouch what he can, between the last sad visit of the honourable practitioner, and the incoming of the undertaker, while the chemist and druggist is given the chance of being thankful for his reverence's sop in the shape of a lotion to be made up. Quacks there will be to the end, in and out of medicine. But their number has become so great that their victims are legion. The public interest demands that those who know how much loss of life, or danger to life, is incurred by misleading advertisements such as we have referred to, should speak out frequently and conspicuously. Public interest at least demands that the composition of proprietary nostrums of all grades and shades should be made known. Those who have spent time and money in acquiring competence and qualification for the practice of medicine and pharmacy must protect themselves. Whatever virtue there may be in any nostrum sold directly to the public without the recommendation of a physician can be obtained with prescriptions made up in the usual way. Medical men should refuse to prescribe such compounds, druggists should cease to sell them. Above all the public must be educated. The quack preys upon ignorance. Ignorance removed, the game of the quack is gone. In the more flagrant cases, if the medical profession and the pharmaceutical body could jointly establish machinery for the purpose, we have no doubt that judicious management would bring impostors to feel the suppressive power of the law.

HANDBOOK TO THE CONFERENCE MEETING AT OXFORD.

With a view to adding somewhat to the interest of the Oxford meeting, the articles that have recently appeared in the Journal on "Oxford and its University" have been carefully revised and reprinted in a separate form. A detailed, anticipatory account of the Conference proceedings has also been added, together with a number of tables of information useful to visitors, and the whole work is fully illustrated with maps and blocks. A copy of this illustrated handbook will be presented to everyone attending the Conference meeting at Oxford, with the compliments of the Editor of this Journal. There will probably be a limited number of surplus copies, and any reader of the Journal who may be unable to attend the meeting, yet is desirous of possessing a copy, is requested to send an intimation to that effect, together with an addressed wrapper, stamped with a three-halfpenny stamp, to the Editorial Department, 17, Bloomsbury Square, W.C. It may be well to state that this handbook is in nowise intended to serve as a guide to Oxford and its places of interest. That purpose is already thoroughly well served by ALDEN'S "Oxford Guide," the larger edition of which is particularly complete, and contains a remarkably fine plan of the city. SHRIMPTON'S "Gossiping Guide to Oxford" is also very good, and SALTRIER'S "Guide to the River Thames" will be found useful in connection with the river excursion. For those who desire to read a connected account of the development, side by side, of the city and its educational foundations, there is no more desirable work than Dr. GOLDWIN SMITH's attractive little book on "Oxford and Her Colleges" (MACMILLAN and Co.), which was largely utilised in the compilation of the articles that have appeared in the Journal.
CONFERENCE MEETING AT OXFORD.
No change has so far been announced in the arrangements for the Conference meeting, which were published in the Journal for July 7 (see p. 7), and they may therefore be regarded as final. The concluding list of papers promised is as follows:—
21. Extract of Indian Hemp, by David Cooper, F.I.C.
22. Laboratory Notes, by F. C. J. Bird.
23. The Keeping Qualities of Certain Samples of Spirit of Nitrous Ether, by H. W. Jones, F.C.S.
24. Note on Extract of Malt with Cod Liver Oil, by H. W. Jones, F.C.S.
27. The Pharmacopoeial Instructions for the Preparation of Tinctures, by R. H. Parker, F.C.S.

DANGERS OF DISINFECTANTS.
A curious instance of the risks engendered by the ignorant use of disinfectants and antisepsis is reported from Leith. There has recently been an epidemic of small-pox at that seaport, and bags or boxes containing camphor have been in great request amongst the inhabitants. One unfortunate individual, however, seems to have been struck with a more original idea, and substituted potassium permanganate for the camphor. The result is apparent from the following:—"I had a small bag of permanganate of potash, a disinfectant, but it got melted with the sweat, and has given me a rather severe burn on the chest. Would you be kind as give me something that will help to take the pain away." This case affords one more instance of the advantages that may accrue if pharmacists introduce the "personal equation" into all sales effected by them, since a few words of inquiry and warning may often prevent injury to the purchaser and give rise to increased faith in the skill of the seller.

PHARMACY ACT CASE AT ST. HELENS.
On the principal that a person charged with an offence against the law is to be given the benefit of any doubt arising as to his capability, the defendant in the case at St. Helens, reported at page 84, has had judgment given in his favour on account of the contradictory evidence given by the witnesses at the hearing of the case. As having an important bearing upon the peculiar conflict of evidence in the case, it seems, however, desirable to state that Mr. Wallbridge,—the local secretary, whose name was so freely mentioned by witnesses for the defence—had no knowledge whatsoever that the case was to be heard. He had no connection with the proceedings from beginning to end, and, as we understand, he obtained his first knowledge of the case from the local newspaper reports. A letter from Mr. Wallbridge appears at page 90.

FEDERATION OF LOCAL ASSOCIATIONS.
According to a circular letter received from Mr. Charles Thompson, Hon. Secretary pro tem., the delegates appointed by the local pharmaceutical associations in connection with the proposed system of federation are requested to meet at the Randolph Hotel, Oxford, at 6 p.m., on Monday, July 30. The business will be (1) to receive the report of the interim committee appointed at Nottingham; (2) to elect officers; (3) general. Should the business not be completed by 8 o'clock, the meeting will adjourn until the following Friday morning at such hour as may be decided upon.

PRESENTATION TO A TEACHER OF PHARMACY.
On Thursday evening, July 19, at Daish's Rooms, South Street, Andrew Street, Edinburgh, Mr. William Duncan, pharmaceutical chemist, apothecary to the Royal Public Dispensary, and teacher of pharmacy, was the recipient of a testimonial subscribed for by a large number of his former students who have qualified as pharmaceutical chemists, or chemists and druggists. Mr. Peter BofA made the presentation, which consisted of a silver tray and tea and coffee service, enclosed in a handsome oak cabinet case. On the tray the following inscription is engraved:—"Presented to William Duncan, Esq., Pharmaceutical Chemist, Royal Dispensary, along with a silver tea and coffee service, by his former students, on the occasion of his marriage, as an expression of their appreciation of his abilities as a teacher, and a token of their sincere esteem. Edinburgh, 19th July, 1894."

SCIENCE SCHOLARSHIPS.
The Edward Jenner Medal and a prize of books—value about twenty pounds—have just been awarded to Mr. G. S. West, son of Mr. Wm. West, a Bradford chemist, as first amongst the advanced students in biology at the Royal College of Science. He has previously had a very successful career, and has now been granted a first-class associateship of the College. His brother, Wm. West, after an equally distinguished career, has recently been elected a Scholar of St. John's College, Cambridge, and a three-year scholarship. Both of the brothers were originally trained for the practice of pharmacy.

ROYAL INSTITUTION.
At the last general meeting of the Royal Institution a donation of £25 was acknowledged from Sir Douglas Galton to the fund for the promotion of experimental research at low temperatures.

UNIVERSITY COLLEGE, LIVERPOOL.
It was announced at the last meeting of the Council of University College, Liverpool, that the Rev. A. S. Thompson had given the sum of £15,000 to build physiological and pathological laboratories.
Transactions of the Pharmaceutical Society of Great Britain.

EXAMINATIONS IN LONDON.

July, 1894.

(Continued from p. 45.)

MINOR EXAMINATION—PASS LIST.

Candidates examined.......................... 291
Failed........................................ 169
Passed........................................ 122

Adams, William Wright................... Birmingham.
Ahier, Ernest................................. Jersey.
Allen, John Harry Stanley.............. Leicester.
Andrews, Morris......................... Stafford.
Aves, Ernest Harold....................... Mansfield.
Baker, John James......................... Jersey.
Barker, Robert............................ Mold.
Beckwith, John Betty................... Liverpool.
Berrill, Edith Annie.................... London.
Bloor, Frederick Arthur.............. Southport.
Blunt, Henry Rowland................. Birmingham.
Blyth, Isabella................................... Sunderland.
Bostock, John.................. Wrexham.
Boyce, Herbert George............. Downham Market.
Brawn, Harry Samuel.................. Spalding.
Breese, John Soley..................... Llandiloos.
Buckingham, Harry................... Coventry.
Burgess, Sydney Robert............ Luton.
Burkett, Walter Vincent.............. York.
Burnage, William Arthur............. Newport, I.W.
Burrell, Benjamin Lawson......... Leeds.
Burrows, Harry............................. Southgate.
Cadman, Charles Thomas............. Blackheath.
Cariss, William......................... York.
Chester, Charles Henry........... Kettering.
Clarke, Thomas Cooper.............. Coventry.
Clarke, Thomas Joseph.................... Derby.
Coleman, John Harold.......... Wolverhampton.
Cooch, Wm. Albert Brooks........ London.
Cooper, George Henry................. Oldham.
Cranton, Edward...................... New Barnet.
Cross, Louis Archibald............. Cambridge.
Cundall, Thomas Bowser........... Pooleington.
Dales, Edward.......................... Louth.
Daniels, Joseph William.......... Landport.
Darling, George William.......... Datchet.
Davies, David Evans............... Pontypriod.
Delaney, Edwin Louis................. London.
Douthwaite, John............. Prudhoe-on-Tyne.
Edwards, Daniel...................... Pontefract.
Ellington, Charles.................. Gosforth.
Elwell, Frederick Budd.......... Landport.
Endall, Edward Albert.......... Brighton.
Evans, Evan Castell................. Llanarth.
Faulkner, William................. Newark.
Felthouse, Arthur George......... Rugeley.
Fellow, John George.......... London.
Flood, Fanny........................... London.
Gau, Ernest George............... London.
Gledhill, William................. Steeton.
Greenhalgh, Edmund Parkinson...... Bolton.
Hague, John.......................... Lincoln.
Hall, Jard Longdon............. Wirksworth.
Harbin, George Albert............. Landport.
Hartland, Charles................. Oldbury.
Hawes, John Geo. Hoadley......... Chichester.
Haythornthwaite, William........ Giggleswick.
Hendry, Alfred Harry............. Hull.
Heasman, William Richard....... Littlehampton.
Hick, Wm. Henry Henwood....... London.
Holmes, John.......................... Bradford.
Horton, William John......... Woburn.
Hough, Thomas...................... Northwich.
Hughes, Job............................. London.
Judd, Samuel Horace.......... Leicester.
Jennings, Cornelius.............. Birmingham.
Jennings, Henry George Herbert.. Bulwell.
John, Alfred.......................... Swansea.
Ring, Ebenezer Thomas............. Reading.
Kitley, Sydney......................... Bath.
Knight, George Thomas......... Shrewsbury.
Lawson, Albert Edward........... Shrewsbury.
Lee, John Cuthbert................. Walsall.
Lewis, David Evan.................. Cardigan.
Little, Thomas......................... London.
Lloyd, Henry Morgan.............. Dowlias.
Lodder, Arthur Edward......... Reading.
Mallin, Elliot Wm. Gravel.......... Soham.
Marsh, Alfred Edward............. Luton.
Nicholls, Ralph..................... Devonport.
Nichols, William Hartley........... Leeds.
Oldham, Harry.......................... Hyde.
Parker, Herbert Charles.............. Slough.
Parker, Wm. Chas. Bland.. Chiarcester.
Perrett, Henry John............... London.
Pitt, Charles Frederick......... Bristol.
Pitt, Geo. Metford Farquharson.. Bristol.
Potter, Thomas Burbridge............ Leicester.
Priestley, Dawson Smith.......... Bradford.
Prior, James Skidall............. Manchester.
Richards, Emrys................... Pontypriod.
Richardson, John Fradil............ Liverpool.
Rymar, Frederick Victor......... Northampton.
Sadler, Walter....................... Tamworth.
Shattock, John Bellis.............. Bradford.
Shorterhouse, Herbert Stephen...... Birmingham.
Simpson, James Hill............... Market Drayton.
Skates, Frank.......................... Bath.
Smedley, Walter Gabriel................. Northampton.
Smith, Philip.......................... Luton.
Sonley, Walter............... Littleborough.
Spinnney, William Frank........ Bournemoutl.
Stevenson, Francis John........... Wolverhampton.
Stanton, Frank Leonard.......... Bridgnorth.
Stow, Norman Vincent.............. Castle Northwick.
Sutton, John.......................... Newport, Mon.
Tapper, Chas. Albert Henry...... Bristol.
Thomas, Charles Herbert......... Shipton Mallet.
Thomas, Hugh Wosley.............. Blackwood.
Thorne, Alfred John............ Tunbridge Wells.
Tims, Edgar Orlando............... Leicester.
Townsend, William Alfred........... Bristol.
Trounson, Herbert James............. London.
Tug, George.......................... Kendal.
Wake, Alfred George... Sheffield.
Ware, Alan Henry..................... Exeter.
Wharram, Thomas Barnard....... Nantwich.
Wolstenholme, Austin Whitley.. York.
Wright, Edward...................... Peterborough.

FIRST EXAMINATION—PASS LIST.

July, 1894.

The College of Preceptors reports that 490 candidates presented themselves for this examination, and that 263 failed. The following are the names of the 227 successful candidates:

Allison, J. W. Woodman........... Cockermouth.
Altars, Moses.................. Manchester.
Angus, James............................... Lerwick.

EXAMINATIONS IN EDINBURGH.
July, 1894.
MINOR EXAMINATION—PASS LIST.
Candiates examined 137
failed 80
passed 57

Allen, John Wilfred ........... Douglas.
Aruniel, Edmund ............... Manchester.
Beachell, John ................. York.
Bradford, James ............... Edinburgh.
Burgess, Frederick William ... Wigan.
Burnett, Charles Johnso ....... Dufftown.
Comrie, William Reed .......... Gravesend.
Craig, William Reid ........... London.
Dalkin, Thomas ................ Sheffield.
Dent, John .................... Manchester.
Fairweather, James Young ..... Forfar.
Forbes, Charles ............... Aberdeen.
Forbes, John Johnston ......... Buckie.
Garbutt, Charles Holmes ..... Shildon.
Hannan, John Wm. Peter ...... Hyde.
Harper, Theophilus ............ Belfast.
Hay, William Fowie ........... Aberdeen.
Hirst, Edward .................. Savile Town.
Hollingworth, Oliver Albert... Barnsley.
Innes, James ................... Glasgow.
Innes, Richard Langlands .. Dumbarton.
Kinch, John Thomas .......... Bolton.
Kitchin, George Shiach ....... Benf.
McCutcheon, David ............ Maybole.
McKenzie, Alex. Thomas...... London.
Milne, Alexander ............. Stonehaven.
Mitchell, Donald ............. Inverness.
Mitchell, William ............. Hyde.
Kapper, Ernest Henry ......... Manchester.
Openshaw, John Wm. Walker... Lower Darwen.
Parry, Lewis .................. Liverpool.
Patterson, Alexander ......... Edinburgh.
Pateerson, Andrew John K. ... Dundee.
Price, George Finlayson ...... Arbuthnot.
Reid, Alexander .............. Aberdeen.
Richardson, Sylvester ......... Reading.
Robinson, Edward George ... Lincoln.
Rook, Moses ................... Maryport.
Rothwell, William Thomas ... Radcliffe.
Rowland, Sidney Comberbach Wrentham.
Sanley, Edward Thompson ....... Littleborough.
Smith, William ............... Edinburgh.
Somerville, George .......... Edinburgh.
Stoddart, Thomas ............. Todmordon.
Strother, Alfred Emmerson... Newcastle-on-Tyne
Stauffer, Thomas .............. Berne.
Sutherland, John George ...... Sunderland.
Symington, James Martin ..... Maryport.
Turner, Calvert Daykin ....... Alfreton.
Walburn, Arthur William ..... West Hartlepool.
Warnock, William Scott ...... Hillesburn.
Williamson, Andrew Arthur. ... Edinburgh.
Williams, James Munro ...... Manchester.
Young, James Clements ...... Manchcster.

2. Describe the process of granulation as applied to official and other preparations, noting conditions essential to success.
3. Comment on (1) glycerinum plumbi subacetatis; (2) emplastrum mentholis; (3) enema magnesi sulfatis; and (4) unguentum hydrargyri nitriti.
4. Give technical Latin for:—Spread on leather; heartburn; headache; the nape of the neck; an hour or so; five drops only.

MATERIA MEDICA.

PROFESSOR HENRY G. GREENE.
Monday, July 23.—Hours from 2 to 5.

[Four Questions only to be attempted.]
1. Discuss the formation of resins, selecting illustrations from the official resins, if possible.
2. What do you understand by the term "essential oil"? Give illustrations of bodies included and excluded. What is the qualitative composition of essential oil of clove, cinnamon, eucalyptus, lavender? Suggest and explain methods for their approximate valuation.
3. From what drug would you propose to isolate hyoscyamine? Give reasons for your selection. Describe in detail the process you would adopt, and give full reasons for each step. In what other drugs does the same alkaloid occur?
4. Compare the constituents of black catechu with those of pale catechu and kino. Explain the relations (if any) that exist between the constituents of each individual drug. Suggest a means for improving the quality of black catechu, and give the grounds upon which the suggestion is based.
5. Describe all the varieties of benzoin with which you are acquainted. Compare them physically and chemically. Give the results of recent work on the chemistry of these resins, and the conclusions to be drawn from them.
6. Describe minutely the characters by which you would recognise the official Jacobsonii leaves. With what substitutes are you acquainted? State carefully the physical characters that enable you to identify each, and, if possible, its geographical source and relative alkaloidal value.

BOTANY.

PROFESSOR REYNOLDS GREENE.
Tuesday, July 24.—Hours from 10 to 1.

[Only three Questions to be answered.]
1. Give an account of the various reproductive cells found in plants. Distinguish between the sexual and the asexual forms.
2. A potato is grown in a dark cellar, without being planted in earth, but being surrounded by moist air. Describe the features the plant will present, and explain them as fully as you can.
3. Describe the changes that may be observed in the cortex of a stem as it increases in thickness. How do you explain the shedding of the bark in the plane tree?
4. Give as concisely as you can a sketch of the De Candollean system of classification. Point out its advantages and defects.

PRACTICAL BOTANY.

PROFESSOR REYNOLDS GREENE.
Tuesday, July 24.—Hours from 2 to 5.

1. Investigate the structure of specimen A. Make preparations of such parts as you consider important, and leave with them lettered explanations.

SCHOOL OF PHARMACY PRIZES
EXAMINATION QUESTIONS.
Session 1893-94.

PHARMACY AND PRACTICAL PHARMACY.
MR. INCE.

Monday, July 23.—Hours from 10 to 1.

1. Write dispensing note on (a) manna; (b) gallic acid; and (c) suppositories of belladonna, indicating necessary precautions.
2. Identify and briefly describe the three microscopic preparations B. C. D. E.  
3. Refer the flowers E. F. G. to their natural orders, giving briefly the reasons for your assignment.

**COUNCIL PRIZES EXAMINATION QUESTIONS.**

*July 25, 1894.*

**BOTANY AND MATERIA MEDICA.**

**Time—10 a.m. to 1 p.m.**

**BOTANY.**

1. Give in a concise manner a descriptive tabulated classification of fruits.
2. Define the following terms:—Asclepias, cymophyllotropous ovules, anthela, dichasium, arillus, gynophore, heterocyst, pseudo-bulb.
3. What influence does the action of light have on the growth of plants?
4. Describe the bordered pitted cells of Coniferae.

**MATERIA MEDICA.**

1. Give an account of the alkaloidal constituents of *Aconitum napellus,* and state howaconitine and issaconitine are separated from the plant, and distinguished from each other.
2. Describe the varieties of ice-pacuanha as met with in commerce, and how the genuine may be distinguished from the spurious. Give the percentage of emetine where present.
3. Give the names, natural orders, and habitats of plants yielding the official oleo-resins.
4. How is the essential oil of bitter almonds formed? What other bodies are produced, and in what manner may the oil be freed from such? Give the tests which distinguish from nitro-benzol.

**CHEMISTRY.**

**Time—2 to 5 p.m.**

1. Mention any weak points you have detected in the usual definitions of an acid.
2. Give the formulae and methods for preparing triethyl stibine and stibethoxide.
3. What is the result of the action of solution of potassium permanganate on methyl-propyl-carbolin? Give formula.
4. What is the action of nascent hydrogen on itaconic, citraconic, and mesaconic acids, respectively? Give formula.
5. Give the graphic formulae of hydroquinone, salicylic acid, and phthalic acid.
6. How many oxides of bismuth are known? Give a method for the preparation of bismuth dioxide in “the wet way.”

**PROCEDINGS OF SOCIETIES IN LONDON.**

**INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.**

At the examination in Practical Chemistry for admission to the Membership of this Institute, held at the laboratories at 30, Bloomsbury Square, from July 2 to 5, twenty-seven candidates presented themselves, of whom the following seventeen were successful:—A. Adams (trained at Mason College, Birmingham); H. Bowes (Assistant to W. Thomson, F.I.C.); B. S. Bull (Christchurch University, New Zealand); O. F. C. Block (Finsbury Technical College, and student under J. Hodgkin, F.I.C.); W. C. Carter (Finsbury Technical College); W. Crossley (Royal College of Science, Dublin); W. R. Hardwick and J. Harger (University College, Liverpool); J. A. Hat-
Now it is here that the whole theory has been put to a most critical test, and the brilliantly successful manner in which it has passed through this ordeal has enormously increased our confidence in its adequacy and usefulness.

Thus the above formulae indicate that there should be another sugar having exactly the same constitution as glucose, with the exception of the CH₂OH and COH groups being inverted. Now such a sugar has actually been artificially prepared by Fischer, for it is not known to exist in nature, and he has given it the name of "galose," an appellation chosen in order to indicate its close relationship to glucose.

I will briefly sketch the evidence upon which our knowledge of this remarkable relationship is based, thus:

1. By gentle oxidation of a sugar of the glucose type the COH group can be converted into a COOH group. When subjected to this treatment glucose and galactose yield two distinct acids, gluconic and galactonic acids respectively, as should be the case assuming the correctness of the above formulae:

\[
\begin{align*}
\text{CH₃OH} & \quad \text{CH₃OH} \\
+ (O)(H)(OH) & \quad - (O)(H)(OH) \\
+ (O)(H)(OH) & \quad + (O)(H)(OH) \\
+ (O)(H)(OH) & \quad + (O)(H)(OH) \\
- (O)(H)(OH) & \quad + (O)(H)(OH) \\
\text{COOH} & \quad \text{COOH}
\end{align*}
\]

Formulas showing the distinction between gluconic and galactonic acids.

2. By the further oxidation of such an acid it is possible to convert the CH₂OH group into a COOH group also, and by applying this treatment to gluconic and galactonic acids respectively, it is found that the product obtained from each is the same, viz., saccharic acid, in precise accordance with what we should be led to anticipate from a consideration of our formulae:

\[
\begin{align*}
\text{COOH} & \quad \text{COOH} \\
+ (O)(H)(OH) & \quad - (O)(H)(OH) \\
+ (O)(H)(OH) & \quad + (O)(H)(OH) \\
+ (O)(H)(OH) & \quad + (O)(H)(OH) \\
- (O)(H)(OH) & \quad + (O)(H)(OH) \\
\text{COOH} & \quad \text{COOH}
\end{align*}
\]

Formulas exhibiting the identity of the saccharic acid obtained from either gluconic or galactonic respectively.

In the following table I have collected the names of all the sugars at present known, and from this it will be seen how greatly the list has been swollen through these classical researches of Emil Fischer, of which I have been endeavouring to give you some account.

**Sugars of the Glucose Type.**

- **Triose.**
  - C₂H₆O₃
  - Glycerose.

- **Tetrose.**
  - C₂H₇O₄
  - Erythrose.

- **Pentose.**
  - Arabinose.*
  - C₇H₁₂O₅
  - Xylose.*
  - Ribose.
  - Rhamnose.* (CH₃C₆H₄O₆).

- **Hexose.**
  - Glucose, d*, l, i.
  - Mannose, d, l, i.
  - Fructose, d*, l, i.
  - C₆H₁₂O₆
  - Galactose, d*, l, i.
  - Sorbinose.*
  - B-Acrose.
  - Talose.
  - Rhamnosehexose (CH₃C₆H₁₁O₇).

- **Heptose.**
  - Mannohexose.
  - Glucoheptose.
  - Galactoheptose.
  - Fructoheptose.
  - Rhamnoheptose (CH₃C₆H₁₂O₇).

- **Octose.**
  - Mannoctose.
  - Glucooctose.

- **Nonose.**
  - C₆H₁₄O₉
  - Mannononose.

N.B.—In the above Table, d = dextroerytrot, l = levotroty, i = inactive. With the exception of those marked * all the above sugars have been discovered by Emil Fischer.

I think it must be admitted that it would be almost impossible to produce more convincing evidence of the enormous power which is conferred upon the investigator by the possession of a carefully framed theory, and when this theory touches some of the most invaluable substances which occur on our earth and leads to their artificial production by the hand of man, it should be possible also for the general public to realize, however faintly, the national duty of encouraging and fostering in every way possible the development of this mighty engine of pure scientific research.

**Recent Additions to our Knowledge of Asymmetric Carbon Atoms.**

Speculation concerning the asymmetric carbon atom and the optical activity to which it gives rise has, however, recently been carried still further.

All who have used the polarimeter are aware that different active substances rotate the plane of polarisation through different angles, and the apparently anomalous circumstance is not unfrequently observed of a simple derivative of an active substance rotating the plane of polarisation in the opposite direction to that of the parent substance. This phenomenon is well exhibited by the following series.

\[\text{Diacetyletartric acid} \quad \ldots \quad -23\text{.1}^\circ\]

Methyl salt of diacetyletartric acid \[\ldots \quad -14\text{.2}^\circ\]

Ethyl \[\ldots \quad +1\text{.0}^\circ\]

Propyl \[\ldots \quad +0\text{.3}^\circ\]

Isobutyryl \[\ldots \quad +10\text{.9}^\circ\]

A most ingenious attempt has recently been made by Crum Brown and Gays to account for these quantitative relations between the rotatory power of different substances by taking into consideration the respective weights of the four groups which are attached to the asymmetric carbon atoms, and arguing that the more nearly equal in weight two of these groups become, the more nearly will optical activity be approached, whilst the greater the disparity in weight of the groups, the greater should the activity be.

These points are exemplified by a series of derivatives of active glycerol acid which I have recently prepared in conjunction with Mr. John MacGregor, and exhibit the following rotations.

| Methyl glycerate H = 1, HO = 17, CH₂OH = 51, 4°-80°C | \[\text{COOCH}_3 = 69\] |

Weights of groups attached to asymmetric carbon atom rotation \([x]_l\).
Ethyl glycerate \[ H=1, \text{HO}=17, \text{CH}_{2} \text{OH}=31, -9.18 \text{ COOC}=73. \]

Propyl (normal) \[ H=1, \text{HO}=17, \text{CH}_{2} \text{OH}=31, -12.94 \text{ COOC}=73. \]

Butyl (normal) \[ H=1, \text{HO}=17, \text{CH}_{2} \text{OH}=31, -18.19 \text{ COOC}=101. \]

Thus, whilst three out of the four groups attached to the asymmetric carbon atom remain constant, the fourth group increases in weight from 59 to 73 to 87 to 101, concurrently with which increase the rotatory power increases also.

In order to put this theory to the test it is obviously of interest to ascertain what is the effect of replacing one of these groups by another group of equal weight. Thus, in the series above, in addition to normal propyl glycerate, we have also prepared isopropyl glycerate, and found its specific rotation to be less than that of the normal, viz., \(-11^\circ.2\). Thus it would appear that the masses of the groups are not necessarily attached directly to the corners of the tetrahedron, but that the centres of gravity of the groups may be at different distances from the corners of the tetrahedron depending upon the internal structure of the groups themselves. Thus, in the case in point this difference in the distance of the centres of gravity of the normal and isopropyl groups is plausibly explicable on the generally acknowledged views of concerning their structure; thus the material interpretation of the formula:

\[
\begin{align*}
\text{CH}_3 & \quad \text{CH}_3 \\
\text{CH}_2 & \quad \text{OH} \\
\text{CH}_3 & \\
\text{CH}_2 & \\
\end{align*}
\]

Normal propyl. Isopropyl.

would indicate that the centre of gravity of the normal propyl should be further from the point of attachment than that of the isopropyl.

There are, however, other cases which find no such ready explanation by this theory, and which lead us to conclude that the theory will have to be materially modified before it embraces all known facts. Thus I have recently prepared in conjunction with Mr. MacGregor the following derivatives of active glyceric acid, which exhibits some very interesting relations:

\[
\begin{align*}
\text{Methyl glycerate} & -1. H=1. 2. \text{HO}=17. 3. \text{CH}_{2} \text{OH}=31. -4.80^\circ. 4. \text{CH}_{3} \text{O.CO}=59. \\
\text{Methyl diacetyl glycerate} & -1. H=1. 2. \text{CH}_{2} \text{CO.O}=59. 3. \text{CH}_{2} \text{CO.OCH}=73. 4. \text{CH}_{3} \text{O.CO}=59. \\
\text{Ethyl diacetyl glycerate} & -1. H=1. 2. \text{CH}_{2} \text{CO.O}=59. 3. \text{CH}_{2} \text{CO.OCH}=73. 4. \text{CH}_{3} \text{CH}_{2} \text{O.CO}=73. \\
\text{Propyl diacetyl glycerate} & -1. H=1. 2. \text{CH}_{2} \text{CO.O}=59. 3. \text{CH}_{2} \text{CO.OCH}=73. 4. \text{CH}_{3} \text{CH}_{2} \text{O.CO}=87. \\
\text{Isobutyl diacetyl glycerate} & -1. H=1. 2. \text{CH}_{2} \text{CO.O}=59. 3. \text{CH}_{2} \text{CO.OCH}=73. 4. \text{CH}_{3} \text{CH}_{2} \text{O.CO}=101. \\
\end{align*}
\]

In this series it will be seen that we have the most interesting relationships between the masses or weights of these groups, to the asymmetric carbon atoms. Thus we start with a compound in which all the groups are of different weight, and in the order:

\[(1) < (2) < (3) < (4)\]

this is followed by:

\[(1) < (2) = (3) < (4)\]

upon which follows:

\[(1) < (2) < (3) = (4)\]

and again:

\[(1) < (2) < (3) < (4)\]

but notwithstanding that the two groups, (2) and (4), are of equal mass in methylisocetyleglycerate, and the two groups, (3) and (4), in isobutyldiacetylglycerate, yet neither of these compounds even approaches inactivity, nor is there any change of sign or direction in the activity exhibited by this series of compounds.

It is evident, therefore, that this more recent extension of the theory of the asymmetric carbon-atom has not yet been so formulated as to fully explain all the known facts. This further development of the theory is, in fact, in that most interesting phase of its evolution, when each new investigation bearing on it is eagerly awaited, to see in how far it will support and strengthen the hypothesis, and in what it will require its change and correction. This is indeed the great advantage of this special series of experiments, as it stimulates investigations and researches which would otherwise have possibly never been made at all, and in this way leads to the earlier and more rapid discovery of all that is true, lasting, and irrefragable.

---

**Parliamentary and Law Proceedings.**

**PROCEEDINGS UNDER THE PHARMACY ACTS.**

**ACTION AGAINST AN UNREGISTERED ASSISTANT.**

On Wednesday, July 18, at the County Court of St. Helens, Lancashire, before his Honour Judge Shand, an action was brought on behalf of the Council of the Pharmaceutical Society of Great Britain, by Mr. Richard Bremridge, the Registrar of the said Council, against John Ernest Edington, assistant at the World's Drug Stores, 135, Westfield Street, St. Helens, to recover £5, the penalty for a breach of the Pharmacy Act, 1888. Mr. T. R. Grey, barrister, instructed by Messrs. Flux, Thompson, and Flux, of London, appeared on behalf of the Society, and Mr. H. L. Riley solicitor, defended.

Mr. Grey, in opening the case, said this was an action for a penalty for the sale of poison contrary to the Pharmacy Act, 1888. The defendant was the assistant to a registered chemist, who carried on business at 135, Westfield Street, and on May 31 he sold a bottle of Dr. Cullis Brown's chlorodyne, that would be proved before his Honour to contain about three-quarters or more of a grain of morphine, which was a poison under the schedule of the Act 31 and 32 Vic., chap. 121. Section 1 made it unlawful for any person to sell or keep open a shop or dispensary for compounding poisons unless he was registered under the Act. Section 2 says that the several articles described in the schedule shall be deemed to be poisons within the meaning of the Act, and his Honour would find on page 24 of the schedule that preparations of morphine were included. The last part of section 2 said that the Society had power to add to the schedule, with the consent of the Privy Council. There were two sections which he would call his Honour's attention to, the first being section 15, which was the section on which they sued that day. This section stated that any person who shall sell or keep an open shop for the retailing, dispensing, or compounding poisons, not being a duly registered pharmaceutical chemist, or chemist and druggist, shall for
every such offence be liable to pay the penalty or sum of £5, which sum may be sued for, recovered, and dealt with in the manner provided by the Pharmacy Act, 1852. Then section 12 of 15 and 16 Vict., said that such penalty may be recovered by the Registrar appointed under the Act in England and Wales by suit in the County Court. Then he need only call him upon his attention that he was selling the Pharmacy Society v. Piper, in which this very substance, chlorodyne—from one of Collins Browne's bottles—was sold, and it was held that the prohibition of the Act against the sale of poison by other than registered chemists extended not only to the sale of such poisons in their simple state, but to the sale of compounds that chemists are authorized to prepare under the Act, and it was also further held that it was not a patent medicine. The only other case that he would refer to was the Pharmaceutical Society v. Wheeler, before Mr. Justice Hawkins, where it was held that when an unregistered chemist's assistant is in the absence of his master sells any poison or preparation containing poison, he is under the Act defined as liable to the penalty under the section, notwithstanding that he effects such sale on behalf of his master, and that his master is duly registered.

In that case, speaking of the object of the Act of 1860, Mr. Justice Hawkins said: "Nothing can be more astonishing than that the object of the Act was beyond all other considerations to provide for the safety of the public, and to guard as far as possible all members of the community from the disastrous consequences so frequently arising from the sale of poison by persons inadequately acquainted with their beneficent properties, and the whole object of the Act would be frustrated away, and the Act itself become a dead letter were we to declare by our judgment that an unqualified assistant can lawfully and with impunity sell any of the poisons to which the Act applies, unless upon each occasion of such sale he acts under personal superstendence of a qualified employer or qualified assistant to such employer. By such personal superstendence we mean not mere presence in the shop or room where the sale takes place, but actual personal superstendence, so that every individual sale shall be so guarded round by the master as to make the assistant and the assistant the safety of every member of the public may be provided for as far as the law can accomplish that object." He would not trouble his Honour any further, but would call the witnesses.

Arthur Foulde said: I am an agent, and reside at 10, Wellington Street, St. Helens. I purchased a bottle of Collins Browne's chlorodyne. That is the bottle (produced) that I bought. It was in that wrapper, and there was a stamp upon the cork. Ernest Edington served me. I paid him 10½d. for it. No one else was in the shop. I afterwards handed it over to Mr. Moon.

Mr. Riley (cross-examining): What are you?—An inquiry agent.

For this Society?—Not for this Society in particular.

And as part of the method to get this compound did you ask Mr. Edington whether he could oblige Mr. Wallbridge with a bottle of Collins Browne's chlorodyne?—No.

Who is Mr. Wallbridge?—I do not know.

Did you mention the name of a local chemist as having sent you?—No.

You say you have got this at wholesale price, 10½d., is it over 12½d.?—I do not know. I got a measure of camphorated chalk and a bottle of Collins Browne's chlorodyne, and he charged me 11½d. for the two.

Had you been in communication with any local chemist?—No.

Then what had directed your attention to St. Helens, and this shop in particular?—I was instructed to visit it by the Pharmaceutical Society.

And you do not know whether they had been in communication with any local chemist—I do not.

When you asked for it did Mr. Edington come round to the case where the propietary articles are kept?—Yes.

Did he then go behind the counter and into the workroom attached to the shop?—No; he never left the shop. I took particular notice.

Was there not his younger brother in the shop?—No. Look round the court and see if you see the defendant.—He is there.

And was not the young man in front of him there as well?—No.

Harry Moon, clerk in the office of the Registrar of the Society, said: On June 7 last I received a packet from the last witness. That is the bottle that was in it. I gave it on July 13 to Mr. Easte for analysis.

Arthur John Easte, analyst and Fellow of the Institute of Chemistry, said: On July 13 I received from the last witness a bottle of Dr. Collins Browne's chlorodyne, and that is the bottle. It was fastened up with the Inland Revenue stamp when I received it. I carefully analysed the contents, and found morphine in it. The quantity of morphine was two grains to the fluid ounces. The bottle contained about three fluid drachms or three-eighths of an ounce, and the actual quantity of morphine in the bottle was three-quarters of a grain. The quantity of morphine in the bottle is enough to kill an adult.

Mr. Riley: I suppose you have often examined this chlorodyne?—Yes; many times.

It is fairly uniform in its quantities?—Yes, it is.

And the directions that are given are sufficient if a person is using it intelligently to avoid this catastrophe of which you have spoken of as possible?—If they follow the directions, yes.

Mr. Grey: That is the case. I simply put the Register in as evidence that he is not registered.

Mr. Riley then addressed the court, and said that his defence would be limited to the question whether the assistant was acting under the personal superstendence of a qualified employer or assistant to such employer. It was not his selling the chlorodyne. They raised no question as to whether it was or was not a poisonous compound. He thought it as well that the witnesses for the prosecution should be called, in order that they might hear all about it. They had heard how the chlorodyne came into the retail shop as a completed preparation, that the care which would need to be exercised, whether by a registered or unregistered person, was obviously not the same as if he were compounding something from his own drug bottles, and were having to apply his intelligence to the matter whether or not it was properly done, so that the application of the dictum of Mr. Justice Hawkins as to the necessity of protecting the public was very much detracted from by that fact. If he showed his Honour that there was on the premises a registered practitioner, to whom the premises belonged, and if the assistant took the bottle from the case and asked his master if he would oblige so and so by letting him have it, he would thus prove that the assistant was acting under the personal superstendence of a qualified employer. Mr. Edington, who was the son of a gentleman who was formerly in business in St. Helens as a chemist, was an assistant to Mr. Peter Webster Harrison, and he would prove that he was on this day in the shop with his younger brother, and that when Foulde came he asked Mr. Harrison if he might let Mr. Wallbridge have the chlorodyne. Having only taken possession of the shop ten days before he went round to the case to see if there was any chlorodyne in stock,
and then took it to his master. That would be sworn to by three witnesses of undoubted respectability, and he thought that his Honour would decide that the sale took place under the direct superintendence of a qualified person.

The defendant was then called and said: My name is John Ernest Edington. I was formerly with my father, who was for many years in business as a chemist.

His Honour: I do not think I have any power to mitigate the penalty, whether the man is a respectable one or not, so that does not matter.

Mr. Riley: I thought it was a circumstance that would have to character.

His Honour: I am sure you are right.

Defendant continuing: On May 31 I was on the premises of Mr. Harrison, who carried on business in Westfield Street under the name of the World's Drug Stores. I believe the business had been carried on up to a few days before by Mr. Alexander Fraser, a registered chemist. I remember Mr. Foulds calling at the stores. At the time he came in I was in the shop and my brother was behind the case. His name is Samuel Percy Edington. Adjoining the shop there is a working room, and Mr. Harrison was there at the bench. When Mr. Foulds came in he said, “Can you let me Mr. Wallbridge have a bottle of Collis Brown's chlorodyne?” and I said “I will see if we have got it.” I took out the key from my pocket and went to the case and saw two bottles. I took one out and went round the counter. The case is on the front of the counter. You have to go to the front of the counter to open it, and the case is pretty well covered with it. Then I went into the room and said to Mr. Harrison, “Can I let Mr. Wallbridge have a bottle of Collis Brown's chlorodyne?” He replied “Yes,” when I said “What will you charge him for it.” He said 10/-, that being 1/2 lower than he generally sold it. I came back from the inner room and told him he could have it, and what the price was. He paid me the 10/-, I do not remember him buying anything else. I entered the sales in a book.

Cross-examined by Mr. Grey: He remembered selling the bottle of chlorodyne to Foulds, but not the camphorated chalk, but if that was entered in the sales he had to pay for it.

His Honour: Did you know that chlorodyne is poison? Witness: Yes, I have made gallons of it.

His Honour: What kind of a case is this that you say your brother was behind?

Witness: It is a high case, and there are show cards on the top of it. It hides the door of the working room.

Samuel Percy Edington said: I have been employed for some time by Mr. Harrison as a traveller. I remember that when the first witness came to the shop and asked if Mr. Harrison could oblige Mr. Wallbridge with a bottle of chlorodyne, my brother went round to the case and got the bottle, and I took it to Mr. Harrison. I was at the shop from nine o'clock in the morning till half-past two, and it was during that time that the transaction took place. Mr. Harrison was doing some chemical analysis in the other room.

By Mr. Grey: He did not know whose name was upon the shop front at the time, but Mr. Harrison’s was not. The reason he knew it was Mr. Foulds that got the bottle of chlorodyne was that he was the only customar in the shop at the time, and he saw his back when he went out.

Peter W. Webber, Mr. Harrison said: I am a registered chemist. On May 31 my firm acquired the business of the World’s Drug Stores. My business and qualification is that of a chemical analyst. On that day I had occasion to be in the room attached to the shop from ten o'clock to half-past twelve. On that day also Mr. John Ernest Edington was engaged as an assistant to me, and at the time I engaged him I told him that he must not on any account sell any poisons unless shown to me personally. I remember during the morning he came and asked me whether I would oblige Mr. Wallbridge with a bottle of Collis Brown’s chlorodyne. I said “Yes,” and he asked me what price I would charge him for it, and I said 10/-. If it was not to him it was to oblige a fellow chemist I should have asked 1/. I took two bottles of chlorodyne over with the stock. One has been sold, and the other is still there.

Mr. Grey: What was not Alice Jones in your employ last year at Prescot?

Witness: No, Agnes Jones was employed there as an apprentice.

Mr. Grey: And she sold oxalic acid?

Witness: Yes.

Mr. Grey: And you had to pay a penalty in this court last year.

Witness: No, we were not responsible. She was fined.

Mr. Riley: In reference to the case of Agnes Jones which has been brought up, at the shop at Prescot you had at that time a registered assistant?

Witness: Yes.

Mr. Grey: Your Honour: We are not trying that.

Mr. Riley: That has been brought in to prejudice Mr. Harrison.

Mr. Grey: In what way?

Mr. Riley: Because the assistant was away getting his tea, and the girl sold some oxalic acid to a neighbour.

Mr. Grey: And the neighbour died.

His Honour: Have you a qualified practitioner at your shop at Boundary Road?

Witness: I am there myself.

His Honour: And you have only one qualified person between two shops?

Witness: Yes.

His Honour: Suppose a person comes to the Westfield Street shop, what happens?

Witness: They send to Boundary Road, that minute is away for me.

His Honour: Is that going on still?

Witness: Yes.

His Honour: Now what things do you insist on the assistant sending over to you for?

Witness: For all articles that are under the Pharmacy Act, and always to dispense any prescriptions that come in.

Mr. Riley then addressed his Honour, and contended that on the evidence the verdict must be for defendant.

Mr. Grey, for the plaintiff society, asked his Honour not to believe the witnesses for the defence. The transaction was quite unknown to Mr. Wallbridge, and Mr. Edington said that Foulds used Wallbridge’s name, though he had sworn that he did not know and had never heard of Mr. Wallbridge.

Foulds was recalled, and re-affirmed his statement that Edington never went out of the shop, and said that the screen or case on the counter was a small one.

His Honour said he thought it was perfectly right that the Pharmaceutical Society should take proceedings in all cases, even of doubt, but he was not going to convict a man—for it was practically a conviction—unless it was abundantly clear that the Act had been breached. If there was a doubt in his mind, thought he ought not to convict. He was not at all satisfied that there had been an offence. He thought there might be a mistake. When they found that door to the inner room was screened off from the shop he was not at all certain that defendant migh
have gone in. If he did, the sale was under the personal supervision of Mr. Harrison. It was for the Society to prove that the sale was not under Mr. Harrison's supervision, and that had not been done. It was a criminal case, and it was perfectly right that anybody who transgressed the Act should be punished, and punished severely, but he must be fully satisfied that wrong had been done before he convicted. To his mind an offence had not been made out. He therefore gave judgment for defendant, with costs.

SALE OF CHLORODYNE BY AN UNREGISTERED ASSISTANT.

At the County Court, held at Manchester, July 25, 1894, before his Honour, Judge Parry, the Pharmaceutical Society of Great Britain sued Arthur Stevenson, of 95, Butler Street, Manchester, for £5, the penalty for a breach of the Pharmacy Act, 1886. Mr. T. R. Grey, instructed by Messrs. Fizx, Thompson and Fizx, appeared for the plaintiff Society. Defendant was not represented.

Mr. Grey announced that he had that morning received a letter, in which the defendant stated that he had no intention of disputing his liability to pay the penalty. The judge, however, desired that Mr. Grey would give him the name of the person who had said that the defendant was an unqualified assistant to a chemist and druggist, and manager of a branch business, and he had sold, on April 14 of this year, a bottle of chlorodyne containing a poison, to wit, morphine, contrary to the provisions of the Act 31 and 32 Vict., cap. 192.

Mr. Grey then explained the provisions of the Act, and directed his Honour's attention to the judgments pronounced in the higher courts in the cases of Pharmaceutical Society v. Piper and Pharmaceutical Society v. Armon.

In reply to a question by his Honour on the case of the Pharmaceutical Society v. Delva, tried in the Manchester County Court last year, Mr. Grey said that that case was decided against the plaintiff Society because no evidence was offered regarding the quantity of poison present in the article—"chloroform." The question would not arise on this occasion because the defendant would prove that there was nearly one grain of morphine present in the article upon the sale of which the present action was instituted.

Mr. Arthur Foulds, private enquiry agent, stated that on April 14 last he went to the shop at 95, Butler Street. It was a chemist's shop. The name over the door and on the labels was J. L. Smith. He asked for chlorodyne, which was supplied to him. He was served by Arthur Stevenson. There was no one else in the shop. He retained the bottle for his possession until May 25, when he handed it to Mr. Moon.

Mr. Harry Moon, clerk in the office of the Pharmaceutical Society, deposed that he had received the bottle from the last witness, and afterwards gave it to the analyst.

Mr. Ernest E. Eales, F.I.C., Demonstrator of Practical Chemistry and assistant to Professor Satal, stated that he had analysed the contents of the bottle produced. It contained three-quarters of an ounce of chlorodyne. He found it in fifteen sixteenths of a grain of morphine. This was a decidedly gross quantity.

Mr. Grey then read Mr. Justice Hawkins's judgment in the case of Pharmaceutical Society v. Wheelock, which was a parallel case with this.

His Honour gave judgment for plaintiffs for £5, with costs.

POISONING CASES AND INQUESTS.

POISONS AT HOSPITALS.

Dr. G. Danford Thomas held an inquest on July 18, at the Marylebone Fever Hospital, on the body of Mary Hope Blake, the child of a domestic servant, who died from carbolic acid poisoning. Miss Amelia Frances McCord, matron at Queen Charlotte's Lying-in Hospital, Marylebone Road, said the child was a few days old. On Friday evening Nurse Reynolds informed the witnesses that she had given the deceased some carbolic acid in mistake for olive oil. The witnesses at once took the child to Dr. Lee, one of the house surgeons, under whose care it remained until it died early on Monday morning. The bottles of medicine were kept in a cupboard in the ward in charge of Nurse Boos, the sister of the floor. The bottles being empty were taken down to be filled. Sister Alice Beedle, finding some time afterwards that the house surgeon had not filled the bottles, filled them herself and replaced them in the cupboard or locker. In filling the bottles Sister Beedle had filled a chemist's stock bottle, labelled "Olive Oil" with carbolic acid. Olive oil and carbolic acid bottles were alike in colour—dark blue—and of a similar size. Nurse Reynolds got hold of the bottle labelled "Olive Oil," but containing carbolic acid, and administered a teaspoonful of the acid to the deceased child in mistake for olive oil. Dr. W. Lee, resident medical officer at the hospital, said he was responsible for the drugs and instruments. It was part of his duty to dispense the drugs. Occasionally, when he was busy and unable to dispense medicines himself, he had entrusted his keys to the sisters—trained nurses—to enable them to procure what they required.

The jury, in returning a verdict of "Death from misadventure," added that, "having heard in evidence that this misadventure arose from one of the nurses filling up at the dispensary a bottle labelled 'Olive Oil' with carbolic acid—a duty which should have been performed by the resident medical officer—draw the attention of the hospital authorities to the occurrence, with a view to their making such amended rules and regulations as may in the future prevent the possibility of such an accident."—St. James's Gazette.

POISONING BY MORPHINE.

The Islington coroner on Saturday, July 31, investigated the death of Andrew Ramsay Gordon, aged 32, St. Christopher's Warehouse, Upper Holloway. It was explained that the deceased had been in the habit of taking morphine muriate to produce sleep. The presence of an abscess in the groin led Dr. Rattray to conclude that it caused great pain, and that death was due to an overdose of morphine taken to alleviate the pain. The jury endorsed the medical testimony by returning a verdict of "Death from misadventure."—Morning.

LIQUID AMMONIA MISTAKEN FOR HEBB TAL.

The borough coroner (Mr. R. Taylor) held an inquest at the New Inn, Halliford Road, Bolton, on July 20, regarding the death of William Hart, aged 76, which took place on Thursday morning. Doctor took some ammonia for Dr. Stott, and his mouth was badly burned.—Dr. Thornley stated that he was called on Sunday morning to meet Dr. Barnes and see the deceased. They found the whole of the mouth and throat red and swollen; and deceased had great difficulty in breathing. All remedies possible were administered. The man日益 worse and died from exhaustion. The coroner said it was a very sad case. He had known the deceased many years, and he was sorry
he had died under such lamentable circumstances. Deceased had lost his sense of smell, and it was certain that he did not know what he was drinking. The jury returned a verdict of "Death from misadventure." The coroner then showed to the jurymen a patent novelty he had received, which it was claimed would prevent, if used, many cases of poisoning. It consisted of a small ball attached to a cork, and if one of these was used for each bottle containing poison, the patient would be warned of its contents (see Ph. J., iii., 1894). Many people use chloral or brandy at night, and if a ball was attached to the bottle there would be no mistake of the wrong medicine being used in the dark. The little appliance, which was very cheap, might save many lives, and like many coroners he had pleasure in recommending its use. It was stated that the life of the late Dr. Tyn dall would have been saved had such an article been in use.—Dr. Thornley considered it a good idea to have a small ball fastened to the cork of every bottle containing poison used in houses, and the jurymen also endorsed this view.—Bolton Journal.

Notes and Queries.

MUSTARD PLasters.

These plasters are frequently spoiled, C. B. Lowe points out, by being dipped in hot water before use, under the impression that their action will thus be intensified. Since, however, the mustard in mustard is coagulated at 140° F., and thus rendered incapable of splitting up the mucous acids, patients should be warned to wet the plasters with tepid water only (Am. Journ. Pharm.).

ADHESIVE PASTES.

Of simple flour pastes that made from rye flour possesses the greatest adhesive power. A much more satisfactory preparation, however, is obtained as follows:—Thoroughly mix wheat flour, 4 ozs., boric acid, 10 grains, and water, 16 ozs. Strain the mixture through a sieve and add nitric acid, 1 dram. Apply heat and stir constantly until thickening occurs, and when the mixture is nearly cold add oil of cloves, 5 drops. The resulting product is highly adhesive and improves in that respect with age. It will keep indefinitely, and even when dry and horny recovers all its former properties on the addition of water. Another useful paste is made by dissolving gum arabic, 2 ozs., in water, 12 ozs., and adding starch, 1 oz., and white sugar, ½ oz. The mixture is then heated on a water-bath until it becomes clear, then several drops of oil of cloves may be added to preserve it. The product will be of the consistency of tar, and should remain so.

HYPODERMIC INJECTIONS OF QUININE.

The following formulas for these injections are given by H. Marty:—(1) Quinine dihydrochlorate, 5 Gm.; distilled water, q.s. to make 10 Cc. Each cubic centimetre will contain 0·50 Gm. of the salt. (Beurmann and Villejean’s formula). (2) Quinine monohydrochlorate, 3 Gm.; antipyrine, 2 Gm.; boiled distilled water (re-cooled to +15°), 6 Cc. The ingredients should be dissolved in the water in a sterilised flask, at a temperature of 40° to 50°, and the volume of the solution made up to 10 Cc. at 18°. One cubic centi-

SODIUM SALICYLATE AND CAFFEINE.

A combination of these substances is prepared by DellaIusa as follows:—Dissolve sodium salicylate, 9·80 Gm., in distilled water 500 Gm., and gradually add caffeine, 15·0 Gm. When complete solution is effected, filter, and evaporate to dryness on a water-bath. The residue forms large, glistening, ivory-like scales, said to contain 62 per cent. of caffeine. They are soluble in their own weight of water at ordinary temperatures (Rev. med-pharm de Constantinople, and Bull. de Pharm. de Bruxelles).

ARSENIC OR ARSENIBER.

"Why should there be a different Latin word for arsenic in the titles 'Liq. Arsenioli Hydrochlor.' and 'Liq. Arsenii et Hydrargyri Iodiode'?—S. C. Reedman." In the first case, arsenious anhydride (arsenious) is referred to, and in the second the element itself (arsenic).

PROPERTY OF HYDRATES.

The following prescription, by an American chemist, has been submitted by Mr. J. Rutherford Hill, as being of interest on account of the uncommon use of the name "propenyl hydrat." for a most familiar compound. The prescription is said to have puzzled a number of pharmacists, and to have been read by some as ordinary "paraphenyl-hydrotat", but reference to a chemical work would have shown that the substance meant is the trivalent alcohol, glycerol, which is the hydrate of propenyl \( \text{CH}_2 = \text{CH}_2 \text{CH}_2 \text{OH} \) just as ordinary alcohol is the hydrate of ethyl \( \text{CH}_3 \text{CH}_2 \text{OH} \).

Obituary.

Notice has been received of the death of the following:—

On June 16, George Munro Baxter, Pharmacetical Chemist, Sydney, Australia. Mr. Baxter was a life member of the Society, and a former student and prizeman in the School of Pharmacy.

On July 4, R. Cade Cuff, Chemist and Druggist, Bristol.

On July 7, Robert Enos Collins, Chemist and Druggist, of Boston. (Aged 39.)

On July 10, John Askew, Chemist and Druggist, of Carnforth. (Aged 61.)

On July 12, Henry Lumsdaine, Chemist and Druggist, of Holborn. (Aged 51.)

On July 16, George B. Gudgeon, Chemist and Druggist, Kimbolton. (Aged 71.)

Books, etc., received.

Correspondence.

The Detection of Sugar in Urine.

Sir,—The paper of Sir George Johnson, on "Some Common Sources of Error in testing for Sugar in the Urine," calls attention to a matter of great practical importance. He and his son, Mr. Stillingsfeet Johnson, have done much in the direction of making the use of the test easier and more reliable, and such additional material will be welcome to many. The subject was discussed at the Society of Public Analysts, when, at my invitation, Mr. Stillingsfeet Johnson was present, and I may perhaps claim to make some observations on Sir George Johnson's paper.

The question of the occurrence of traces of sugar in normal human urine has been the occasion of much controversy, and the last word still remains to be said. Brücke appears to have been the first to state that all normal urines contain sugar, and this view was supported by Bonne-Jones, and by Kühne, but opposed by Friedlander, Wunderbald, Measner, and Babo. The question was re-examined in 1878, when, who pointed out many fallacies in the methods of those who had found sugar and concluded that it was either absent from normal human urines, or in such small proportion that the then used methods were insufficient for its positive recognition in the presence of substances which interfere with many of its reactions. On the other hand, Dr. F. W. Pavy, in 1876, concluded that sugar was a normal constituent of urine, and that no sharp line of demarcation could be drawn between the excretion in health and in disease, except quantitatively. Molisch, again, from the examination of a large number of samples of urine from healthy persons by the alpha-naphthol and thymol tests, came to the conclusion that traces of sugar are met with frequently in human urines, although the value of this and hence the accuracy of his conclusions have been disputed by Leblanc and also by Seegm. (Journ. Soc. Chem. Ind., xxvi., 24, 1883.) E. Luther, also, as the result of the application of the ferric and alpha-naphthol tests to a large number of samples, concludes that glucose is present in all human urines, the amount found in the excretion of urines averaging 0.1 per cent., while the total carbohydrates amount to 0.3 per cent. (Chem. Centr., xvi., 1882, p. 96; and Journ. Chem. Soc., lxxii., 1559.) According to E. Moes (Zeitschr. physiol. Chem., xxvii., 518), the normal urines of the dog, horse, and rabbit always contain more or less carbamides, as is also shown by the ferric-Naphthol reaction and confirmed by the benzoin test, and this is due to the fact that urines of these animals are found to be slightly lactonitric. By the production of the crystalline phenyl-glucose-pseudo-acid a method from the objections and fallacies which underlie nearly all other tests—I have proved to my own satisfaction that minute quantities of sugar are present in some specimens of urine from persons apparently in perfect health.

Pavy, in a letter published in the Lancet for July 14, says it is a very pertinent question, if the crystalline causes yielded by many samples of normal urine when treated by the phenyl-hydrasine test be not indicative of sugar, to what body must its formation be ascribed? Of course, if sugar and its compounds are known to give a crystalline compound with the phenyl-hydrasine test, and they do not appear to exist in healthy urine. The fact appears to be that while normal human urines contain traces of sugar, which certainly appears there almost constantly present, sugar has not been found in the urine constantly present, and a great number of the abnormalities recording its occurrence are quite inconclusive.

Head cases of non-occurrence do not disprove the occasional compound with the phenyl-hydrasine test, but they do not appear to exist in healthy urine. The fact appears to be that while normal human urines contain traces of sugar, which certainly appears there almost constantly present, sugar has not been found in the urine constantly present, and a great number of the abnormalities recording its occurrence are quite inconclusive.

C. H. C. M. H. Johnson, his son, I gather that they both hold a strong negative opinion as to the existence of sugar in normal urine. This opinion appears to be largely based on the results obtained by examining urine from which all uric acid and creatinine have been previously removed by suitable methods with hydrochloric acid. I have had a considerable experience of the mercuric chloride method, which was originally proposed by Meku, but has now been improved by Mr. Stillingsfeet Johnson. His process of removing the creatinine, by boiling the urine for four minutes, allowing it to stand for some days at the ordinary temperature, is, I believe, a direct outcome of my objection to the time required for its separation. There is no question that the process of examination, directed by Mr. G. S. Johnson in presence of sodium acetate, so that potentially mercurocete is the reagent employed, is one of the most perfect precipitants which can be used. The urine is precipitated in the cold, and the mucilage and urates of the urine, together with the xanthine bases, colouring matters, and any albuminous matters which may be present; while on standing or boiling the creatinine is precipitated. I prefer to add solid mercuric chloride and sodium acetate to the urine instead of using solutions of these substances, but this is a detail. Mr. G. S. Johnson, however, both in his published papers and in his letters to me, recommends the use of a saturated solution of mercuric chloride in the presence of sodium acetate. I have compared four of the urines. Sir George, on the contrary, prescribes the very large proportion of nineteen-twentieths. I have found the subsequent removal of the excess of mercury in the following manner: I add ammonium, which, according to Mr. G. S. Johnson, should be dilute and added drop by drop, avoiding an excess, but, according to his father, should be employed strongly, and in the amount of a grain of uric acid. I have perfectly removed at this stage, the subsequent estimation of the sugar by titration with Pavy's copper solution becomes impossible or inaccurate. Hence I have found it preferable to remove the excess of mercury by boiling for a few minutes with sodium acetate. I add to the filtrate I add a considerable excess of ammonium, which keeps the urine in permanent solution, and I have found that neither the ammonium nor the sodium salts introduced materially affect the accuracy of the determination. I have obtained excellent agreements in experiments, otherwise similar, in some of which sucrose in and others ammonium was used to precipitate the mercury. Both the curious point is that, in case one of the somewhat limited number of samples of urine from presumably healthy persons which I have hitherto examined by the mercuric chloride process, a small quantity of sugar has been indicated by the result of the above test. In the case of one of these urines, the result indicated as 0.05 per cent. of the urine, but a wholly negative result was never obtained. Of course, the Pavy titration, even when conducted on urine which has been put through the mercuric chloride process, does not always afford the proof of the presence of sugar; but the samples which gave these small indications of apparent sugar yielded crystals of glucosone by the phenyl-hydrasine test, and this fact is not capable of being readily explained away. On the other hand, Mr. G. S. Johnson states that, after subjecting to the mercuric chloride treatment, healthy human urine gives no indication of sugar by the Pavy reaction, or at any rate he affirms that no trace of sugar then exists in the urine. In this case it would be possible to add an infinitely large volume of the treated urine to a limited volume of Pavy's solution without the blue colour being lessened or destroyed. It would be interesting to learn from Mr. Johnson whether he has actually found this to be the ease. As explained by Sir G. Johnson in his paper, the presence of creatinine in normal urine causes the production of a red coloration with an alkaline picro acid solution, and this fact shows that, however convenient picro acid may be for the rough determination of sugar in typical diabetic urine, it is useless as a test for the traces of sugar alleged to be sometimes present in the excretion of healthy persons.

Sir George attempts to explain away the similar colour due to the creatinine. It is true that the normal proportion and variation of the creatinine of urine have been far less studied than that of the uric acid, although the former is present in considerably greater amount. This is not the point. The sugar in diabetics makes themselves evident very readily, while their
physical characters give them great pathological significance. On the other hand, kreatinine affords no indication of its presence to the casual observer, and its physiological and pathological significance are very imperfectly understood. According to Mr. G. Stillingfleet, the excretion of kreatinins varies largely with the diet, being greater when this is of a highly nitrogenous character. Taking Mr. G. S. Johnson's figure of 2 grammes daily, and accepting his statement that the copper-reducing power of urine varies in the ratio of to that of 1-8 grammes of copper, or about 55 grains of glucose, it follows that normal urine will exert a copper-reducing power corresponding to 0-5 grain per ounce, and the reduction from the same cause is likely under a highly nitrogenous diet to reach two or three times this proportion. This amount will seem very insignificant to those who are in the habit of dealing with typical diabetic urine containing fifty times as much, but it is by no means negligible when small quantities of true sugar are in question, or when it is sought to ascertain with certainty whether traces of sugar are sometimes present in normal human urine. Now that we possess a means by which kreatinine may be readily and completely removed from urine, it appears to me a pity to attempt to apply the picric acid test for sugar in its presence, as is proposed by Sir G. Johnson. In my opinion, it is far preferable to remove the kreatinines by the mercuro- chloride treatment and then test for sugar in the filtrate, after removing the excess of mercury. If this be effected by boiling with zinc-dust, as already described, the filtered liquid is well fitted for the determination of sugar, either by the volumetric copper process of Pavly or the colorimetric method with picric acid advocated by Sir George Johnson. I may here mention a modification of Pavly's process which commands itself for use by the use of special apparatus. To avoid this disadvantage I have devised the following form of the test:—An accurately measured volume of 10 c.c. or 100 minims of Pavly's ammoniacal copper solution, prepared in the usual way, is placed in a wide test-tube, and ten or twelve drops of petroleum or paraffin burning oil added. This forms an upper layer which effectively excludes the air. The test-tube is inserted into the neck of a wide-mouthed bottle containing hot water, which is maintained at a constant temperature, and heated until the contents of the test-tube have reached the point of ebullition. It is desirable to add a few fragments of broken clay tobacco-pipe to the contents of the test-tube in order to hasten the evaporation. The urine to be tested is treated with an equal measure of ammonia and filtered from the precipitated phosphates. A known volume of the filtrate is then further diluted with water according to the proportion of sugar supposed to be present, and then added drop by drop to the boiling hot Pavly's solution by means of a small burette or graduated pipette, until the disappearance of the blue colour indicates the termination of the reaction. If 10 c.c. of Pavly's solution were employed, the volume of urine required to decolourise it contains 0'005 grammes of sugar; or if 100 grammes of the copper solution were used the urine contained 0'0005 grammes of sugar. By this means it is possible, in the foregoing manner, fair approximate determinations of sugar are obtainable very rapidly and with the simplest of apparatus. Experiments in my laboratory by Mr. G. Bernard Brook show that urine from healthy persons excrete Pavly's solution a reducing action equal to that of a liquid containing from 0'1 to 0'5 per cent., or 0'4 to 1'3 grain per ounce, of sugar. Of course this reduction is not due entirely to actual sugar, the kreatinine and uric acid being accountable for a greater part of the.

Alfred H. Allen.

A Barre Defense.

Sir,—Permit me, through your columns, to make a note or two on the recent action at St. Helen's, which you and I intended publishing in detail in the next issue of the Pharmaceutical Journal. In the cross-examination of the defendant, he first stated that your agent (Mr. Foulds) said that the "chlorodyne was for Mr. Wallbridge," neither know, nor have I seen, Mr. Foulds. I do not know Mr. Harrison, and I have never sent to his shop at any time for any article, consequently the statement that "occasionally sent" was an untruth, which ought to be exposed, as it might prejudice a certain section of the public. His other remark is extremely prejudicial, is it likely, I think they would have been likely to say for a "cask," than they would have sent a bottle containing a scheduled poison if my name was not mentioned in the matter? I say no! these statements are in entire opposition to each other. The presumption that I sent for the article is based only upon the fact that I am the local secretary. Further, in conclusion, I did not even inform of the man as, being only a few yards away, information would savour too much of personal animosity. J. G. Wallbridge.

St. Helen's. Local Secretary.

Answers to Correspondents, etc.

M. P. S.—Yes! It is Leonurus cardiaca.

Diary of the W itch.

Monday, July 30.
British Pharmaceutical Conference (Oxford Meeting).
Meeting of the Executive Committee at the Randolph Hotel, at 6 p.m.
Reception by the President and Conversations in Christ Church Hall, at 8.30 p.m.
Federations of Local Pharmaceutical Associations.
Meeting of Delegates at the Randolph Hotel, Oxford, at 6 p.m.

Tuesday, July 31.
British Pharmaceutical Conference (Oxford Meeting).
Sessions of Conference in the Hall of Balliol College, at 10 a.m.
Luncheon at the Randolph Hotel, at 1 p.m.
Sessions of Conference, at 2 p.m.
Garden Party in the grounds of New College, at 4.30 p.m.

Wednesday, August 1.
British Pharmaceutical Conference (Oxford Meeting).
Sessions of Conference, at 10 a.m.
Luncheon at the Randolph Hotel, at 1 p.m.
Sessions of Conference, at 2 p.m.
Visits to various Colleges, the City, etc., at 4.15 p.m.
Smoking Concert at the Randolph Hotel, at 9 p.m.

Thursday, August 2.
British Pharmaceutical Conference (Oxford Meeting).
River excursion to Abingdon, leaving from Folly Bridge, at 8 a.m.
Luncheon in the Council Chamber, Abingdon, at 1.30 p.m.
Boats leave Abingdon, at 3 p.m.
Visit to Nuneham Park, at 4 p.m.
Tea on board the boats, at 6 p.m.
Arrival at Oxford, at 8 p.m.

Friday, August 3.
Quoetts Microscopical Club, at 7 p.m.
Exhibition of Objects.

advantage of his position to speak to the members 
ex cathedra. In answer to the question whether 
the condition of pharmacy in its own special 
domain is satisfactory at the present time, 
he was compelled to speak in the negative, 
but he argued that this is in very great 
measure due to certain peculiar directions in which 
the trade in medicines has developed in recent 
years, and that the Pharmaceutical Society is most 
certainly in no degree to blame for the present 
condition of affairs. It is rather registered chemists 
and druggists who are to blame, for endorsing 
the falsehoods of advertising quacks and helping to 
create on the part of the public an enormous and 
unhealthy demand for proprietary medicines. The 
manner in which medical practitioners are 
invigiled into recommending and prescribing quack 
remedies was also forcibly declaimed against.

Returning to pharmacy, Mr. Martin expressed the 
opinion that a grave mistake was made when powe 
was given, under the fifth section of the Pharmacy 
Act, 1868, to place on the Register without ex-
amination or fee all who claimed to have been in 
business as chemists and druggists prior to Decem-
ber 31, 1868. The baneful influence of the purely 
trade element is still on the Register, and threaten 
to overthrow the very principle to support which 
the Pharmacy Act was obtained. It is impossible, 
it was pointed out, in the practice of pharmacy, to 
grasp commercial advantages and yet retain the 
rewards properly belonging to professional services, 
and pharmacy must shortly make its choice be-
tween the two. The very essence of trade is that it 
is capable of indefinite expansion, and there is no 
limit to the extent to which a tradesman may sell 
his goods through the agency of others. But in-
definite expansion is impossible in the fulfilment 
of the proper functions of pharmacy, which 
stamp it as a profession rather than a trade, 
requiring its members to receive a special 
education and give evidence before a legally con-
stituted body that they have been so educated. 
The service rendered, also, is personal and direct.

The non-recognition of the professional status of 
pharmacists is undoubtedly due, said Mr. Martin, 
to the preponderance of the trade element and the 
commercial spirit amongst registered men, and 
this has handicapped the Pharmaceutical Society, 
rendering it difficult for it to advance upon the 
lines and in the spirit of the Pharmacy Act. Phar-
macy as a trade is a failure, and rightly so, as noth-
thing can justify the use of professional knowledge to 
excite men's fears and play upon human credulity 
for gain. Regarding the steps which should be 
taken to enable pharmacy to realise its privilege 
and accept its responsibilities as a profession, it was 
recommended that the entrance examination should 
be made a more stringent test of intellectual powers 
and school training. Algebra, geometry, history,
geography, and a modern language should be included in the syllabus, and an extended knowledge of Latin should be required. The examination should not be passed before the age of seventeen, and should be followed by a three years’ actual apprenticeship. An enforced curriculum covering two years should then precede the qualifying examination, lasting a week or more, and success in this should carry with it the qualification and title of pharmacist.

The question of recompense for all this, however, must be left to the future, as pharmacy must not expect to receive its reward before it has properly equipped itself for service. If the pharmacist will but continue unremittingly in his endeavours to raise himself, the dispensing of medicine is bound to come to him in the natural course of things. As to the principle upon which the remuneration of the pharmacist should be based, Mr. Martin was very decided. The dispensing chemist, he said, must be paid at a rate which will enable him to get his living honestly and openly, and render him superior to the temptation to increase his profit by tampering with the quality of what he sells. His remuneration should also enable him to devote a proper amount of time and care to his work, and so eliminate a very real source of danger consequent upon the haste and bustle of trade methods.

After briefly referring to certain points where improvement might be effected in Conference matters, Mr. Martin brought to a close an address which merits the fullest consideration from all British pharmacists. The evils complained of by him are of long standing and may require sharp treatment, but it is above all things desirable that all engaged in pharmacy should be fully aware of their existence, and the extent to which they check healthy development.

Vote of thanks was proposed by Mr. Michael Cartwright, President of the Pharmaceutical Society and Vice-President of the Conference. He described the address as one of the most able to which he had ever listened, and spoke of the peculiar appropriateness of the fact that it had been delivered by one hailing from Newcastle-on-Tyne, where the Conference first met, and that it embodied similar ideas to those so ably propagated in former years by the late Henry B. Brady, who was also a Newcastle pharmacist. Mr. Druce having briefly seconded the motion, it was supported in eloquent terms by Sir Henry Acland, after which the vote was unanimously accorded.

The reception of delegates then took place, and was followed by the reading of the report of the Executive Committee by Mr. Naylor (Honorary Secretary). In presenting the thirty-first annual report, the Committee was able to state that general interest in the work of the Conference shows no sign of diminution. Increased membership is still, however, a desideratum, for although the last two annual meetings have been exceptionally well attended, the number of enrolled members represents no marked increase. With the view of bringing the Blue List up to date, it has been completely revised by a sub-committee appointed by the Executive. Several new subjects have been introduced, the majority of which are specially adapted for investigation by pharmacists, while others have been expunged. Only one application for a money grant in aid of research has been received during the year, the sum of £3 having been granted to Mr. H. Bowden in furtherance of his investigation of Hemisemia indica. Mr. A. Cripps has been unable during the year to continue his work on Ipecacuanha, for which grants have been previously made to him, but he hopes shortly to resume his examination of this drug. Mr. W. Elborne, B.A., who was last year the recipient of a grant, is also unable at the present time to supply a further instalment of his work on octo bark. The Conference has lost by death several valued members during the past year. Of these, Professor Bentley was probably the most widely known. He was one of the founders of the Conference, and filled the office of President for two consecutive years—at Nottingham in 1888, and at Dundee in 1897. His long association with pharmacy as a professor, and his devoted enthusiasm for botany, brought him into contact with distinguished men from all parts of the world. His works on botany and materia medica have long been and still are justly valued. In the last annual report reference was made to the resignation of Mr. R. H. Davies, as Honorary Treasurer of the Conference, owing to prolonged illness. In recognition of his services he was last year elected Vice-President. To the deep regret of his numerous friends the illness terminated fatally. Professor J. M. Maisch, of Philadelphia, an honorary member of the Conference, and the author of valuable pharmaceutical works, also died last autumn shortly after receiving the Hanbury medal. For twenty-six years he had acted as permanent Secretary to the American Pharmaceutical Association. Lastly, the Committee had to record the loss of Mr. W. D. Savage, of Brighton, a veteran pharmacist and former Vice-President of the Conference, whose death took place only a few weeks ago. Through the decease of Mr. R. H. Davies a vacancy occurred in the Vice-Presidency, to fill which the Committee elected Mr. J. H. Mathews, of London. Two honorary members have also been elected during the year, Professor Joseph P. Remington.
of the Philadelphia College of Pharmacy, and Dr. ANTON von WALDHUM, President of the
Premium of Pharmacists of Vienna.

The financial statement for the year,
and the report of the Treasurer of the
"Bell and Hills' Library Fund," were
next read. The first showed that the position of the Conference in this respect was fairly satis-
factory, a small balance being left in hand. The
main item of expenditure was, as usual, the cost of
publication of the 'Year-Book.' In presenting
the statement, the Hon. Treasurer, Mr. JOHN
Moe, endorsed what had been said in reference to
the late R. H. DAVIES, and urged that the best
way of improving the financial position was for
members to induce others to join the Conference.

The report of the Unofficial
Formulary Committee, read by Mr.
MARTINDALE, stated that since the
last meeting of the Conference a new edition
of the Formulary had been produced and
was now on sale. Four new formulæ have been
added, viz., 'Colloidium Stypoticum,' 'Extractum
Belladonnae Polii Alcoholicum,' 'Liquor Bromo-
chlorid Solvens,' and 'Syrups Acidum Hydriodicum.'

Other alterations consist chiefly in lessening the
quantity of certain syrups, and in an improved
formula for 'Colloidium Belladonnae,' which is now
directed to be made from a solid alcoholic extract
of belladonna leaf, assayed at the time it is used
so as to obtain a uniform product, instead of from
a liquid extract.

The reading of papers was then proceeded with,
in the order of the following abstracts:—

During the progress of their work
on tinctures, Messrs. FARR and WRIGHT
preserved specimens of each
of those operated upon, with the in-
tention of turning their attention later to the
question whether or not tinctures, whose active
principles can be readily and accurately deter-
mined, suffer any diminution in strength when
kept for a length of time. A number of the tinc-
tures have now been examined, after being kept
for periods ranging from twelve months to three
years, and the results obtained prove that the
strength of the alkaloidal tinctures, so far as can
be judged from the determination of their alka-
loid constituents, remains approximately the
same for a considerable length of time. It may
nearly be assumed, therefore, according to Messrs.
FARR and WRIGHT, that when preserved under
normal conditions such tinctures remain constant
composition. A tabular statement was submitted
and showed the results of the examination of tinc-
tures of aconite, belladonna, cinchona, colchicum,
laudanum, glycerrhiza, hysocyamus, jaborandi,
scilla, stramonium, and veratrum viride. The
by notable instances of loss of alkaloid were in
the case of the tinctures of cinchona and veratrum,
the loss being probably due to mechanical action,
and in the most extreme case the average loss did
not amount to 5 per cent.

In the course of the same work on
determination of tinctures, Messrs. FARR and WRIGHT
of Alkaloids in employed gravimetric processes for
Tinctures, determining their alkaloidal contents.
CASPARI and DOHENY, however, read a
paper before the American Pharmaceutical Asso-
ciation last year, in which it was claimed that the
determination of alkaloids in galenical preparations
may be effected more accurately by titration than
by weighing. In order to ascertain whether this
assertion had any foundation in fact, the English
workers performed an elaborate series of experi-
ments, the results of which go to prove that volu-
metric methods are useless in the case of aconite
and colchicum; unsatisfactory with cinchona and
veratrum; but of greater value for belladonna,
hembane, stramonium, conium, jaborandi, lobelia,
nux vomica, and opium. In the case of gelsemium
the figures showing the comparative results ob-
tained by the two processes accord very closely.
As a general process, a method of volumetric
determination was described, which may "be
found in some cases almost equally reliable and
somewhat more expeditious than gravimetric pro-
ceses," but it was maintained, in conclusion, "that the results yielded by the latter are, if any-
thing, the more reliable of the two."

Preparation of a typical dentifrice,
adapted to general use, were formu-
lated in a paper by Mr. A. TURNER,
D.S. As a mechanical base chalk
is to be preferred, "prepared" rather than "pre-
cipitated," powdered pumice and charcoal being re-
jected on account of possessing various undesirable
properties. The prepared chalk should be free from
silica, a little sodium bicarbonate may be added to it
to give increased antacidity, and oil of cinnamon
should be used as an antiseptic. Astringent sub-
stances should not be employed in tooth-powders,
and colouring matter, if used at all, should be harm-
less and neutral. The finished dentifrice is best
put up in wide mouthed bottles with sprinklers,
labelled with full directions for use.

Extracts A method was then suggested by
Mr. E. W. LUCAS for the economical
Nux Vomica preparation of an extract of nux
vomica which, while firm in consistence and free
from oil, shall be little liable to loss by evaporation.
The process consists in macerating nux vomica in
fine powder, 16 oz., for four days in chloroform
water, 2 pints, to which acetic acid, 2 fluid oz.,
has been added. Percolation is then performed
and continued by adding more chloroform water
until a gallon has been collected. The percolate is
next evaporated at a low temperature to 4 oz. by
weight, glycerin, + c. by weight, being added towards the end of the operation. Finally, the alkaloids are determined in the usual way and the extract is brought to the required standard. To prepare the corresponding dry extract, the glycerin is omitted and the evaporation continued as far as possible on a water-bath, the residual water being afterwards driven off by means of a hot oven or drying chamber. The dried product should be rapidly powdered and mixed with sufficient liquorice or other inert powder to bring it to the required strength, after which it must be preserved in small vials, hermetically sealed.

The next paper embodied the results of determinations of the active constituents of the seeds of Strychnos ignatia, Lind., which have been made by Mr. F. Ransom, for the sake of comparison with nux vomica seeds, the methods employed being those of Dunstan and Short. As a result it appears that, although the seeds of S. ignatia may occasionally contain a larger proportion of strychnine, as compared with brucine, than those of nux vomica, the percentage is more variable, and the average percentage of total alkaloid is considerably less. The glucoseide, loganin, discovered in nux vomica by Dunstan and Short, appears also to be present in ignatia. Mr. Ransom suggested that the results of the investigation indicate that nux vomica is the better adapted for pharmaceutical preparations, and that ignatia is not likely to prove of much value for medicinal purposes, though it may be used for the occasional extraction of strychnine.

Remarks on Attention was next drawn to the genus Gnetum (Gnetaceae) by Mr. W. Elborne, who referred to the fact that the stems of plants belonging to it possess internally the remarkable ringed structure characteristic of the natural order Manispermae, and are consequently not unlike that of Pareira brava. The only other point in this somewhat nondescript paper was that while "Abuta" and "Butua" are popular Brazilian terms for Pareira brava and Abuta, Aubl., an allied genus, the genus Abutua, Lour., is yet synonymous with Gnetum, L.

An important subject to pharmacists was then introduced by Mr. R. H. Parker, in his paper on the recovery of residual tinctures from marc. As he pointed out, the best method to be employed for this purpose must depend to a great extent upon the quantity of material under operation, and the kind of apparatus available. The question was considered with reference to the preparation of not more than four pints of tincture with such apparatus as may be found in any pharmacy, pressure and displacement by water being the two methods described as available under these conditions. Using pressure, the best results are obtained when the quantity of marc reaches the maximum capacity of the tincture press, a result almost equal to those produced by hydraulic power may be obtained with a screw-press, if the cup for receiving the marc is comparatively narrow and nearly filled. Displacement by water was next considered, and comparative experiments in "downward" and "upward" displacement were described and illustrated sketches. The results in the two cases were shown by a tabular statement to be nearly identical. Other results described were of experiments in displacement by water versus displacement by alcohol and displacement of proof spirit and chloroform respectively by water. The deductions made from the different results are that the precision of displacement depends upon the relative affinities of the superposed fluids and their miscibility at the surface of contact; and that in the downward displacement of alcoholic tinctures by water, diffusion in the rate of percolation takes place to an inconsiderable extent only. In conclusion, Mr. Parker made several suggestions regarding the chief points to be observed in order to secure good results in the process of percolation, and displacement by water, which was asserted to be much more economical than screw pressure, a small scale, and quite reliable if carefully conducted, though better adapted to preparations made with strong spirit than those made with proof spirit.

Preparation of Tinctures, altogether calculated to ensure uniformity of product, under variety of manipulations, Mr. R. H. Parker further suggested that all tinctures and similar preparations of about the strengths of 1 in 8 should be directed to be made by maceration only, without final adjustment of quantity; that of 1 in 4 or greater strength "to be prepared by percolation, so that N fluid parts of percolate represent the activity of one part of drug." The pharmacist would then be left to select his method of recovering the residual spirit, according to the quantity of materials dealt with.

Practical information on several points was furnished by Mr. F. C. Bird in the first paper read on the second day of the sessions of the reference. It was stated that the property possessed by compounds of stearic acid with the alkaline metal of forming gelatinous solutions with water—a small proportion of dissolved stearic soap suffice to render a liquid almost solid—had been turned to account in the preparation of a liniment containing turpentine and ammonia in such proportions as had proved difficult to combine by means of sapo mollis. The method followed was to solve the stearic acid in the turpentine, add
ammonia mixed with distilled water, and agitate. A milk-white emulsion of turpentine was instantly produced, and showed no tendency to separate. The following formula was proposed for lin. terebenth. B.P. :– oil of turpentine, 16 fl. ozs.; camphor, 1 oz.; stearic acid, 50 grains; solution of potash, ½ fl. oz.; distilled water, 1½ fl. oz. The acid is melted on a water-bath with a little of the turpentine, and the mixture added to the remainder of the latter, in which the camphor is dissolved. The solution of potash and water are then mixed, the turpentine solution added, and the whole agitated until properly combined. The second note dealt with the purification of distilled water prepared on the continuous principle, by forcing it from ammonia. The plan recommended is to add before distillation potassium bichromate, 10 grains, and sulphuric acid, 6 fluid drachms, for each gallon of the still's capacity. The distillate is colourless, and answers the B.P. tests. The purified distilled water should be kept in a large glass bottle with stoneware stop and narrow neck, the latter being plugged with cotton wool and surrounded by a loosely-fitting tin cap. Under these conditions it may be preserved indefinitely without change, however the temperature may vary. In a third note it was suggested that the sulphured odour sometimes developed by syrup. hypophosph. se, B.P.C, was due to the fact that commercial calcium and manganese hypophosphites are rarely free from sulphate. The last note dealt with the advantages and disadvantages of re-percolation, as a B.P. process, details being given of several experiments in which that method of exhaustion had been applied.

Four well-known brands of extract of malt with cod liver oil have been examined by Mr. H. W. Jones, whose paper came next in order. That preparation is regularly supposed to contain half its bulk of oil, but the results stated in the following table show that this is far from being the case:

<table>
<thead>

Preservation To test the keeping qualities of spirit of nitrous ether, under specially good conditions, Mr. H. W. Jones set aside a number of samples at the beginning of 1893, and now described the results. The stoppers of the bottles were luted and tied over with leather, and the bottles were subsequently kept in a cool dark, undisputed, for fourteen to fifteen months. Examining the contents the loss of ethyl nitrite was found to be considerably less than anticipated.

This loss, though mainly due to evaporation, was probably to some extent due to the presence of water. In the only sample exceeding the limit of the B.P. as regards specific gravity (No. 9 in table) a notable change was apparent, as shown by the figures:

With a view to rendering the nature of Oxford, etc., features of the district more intelligible to visitors, Mr. G. C. Druc, M.A., next gave some brief descriptive notes on the geology, botany, and river systems of Oxford and neighbourhood, attention being directed chiefly to the geological formations and the occurrence and habitats of rare plants.

In the following paper Mr. C.E. Stuart, B.Sc., referred to the large amount of attention recently directed to the use of extracts of various animal substances in the treatment of disease, doubtless consequent on the success of the treatment of myxodema by thyroid extract. He gave a short review of the theories which have been proposed to account for the action of these extracts, and explained his formula and methods of preparing several of the preparations, namely those from brain, spinal cord, supra-renal capsule, pituitary body, thymus, kidney, and bone marrow. He exhibited a powder prepared by repeated aqueous extraction and alcoholic precipitation of sheep's thyroid glands, which is now being experimented upon with regard to its activity. With respect to an improved formula for thyroid extract, he thought that there is no evidence that any method of preparing it gives better results than Dr. G. Murray's original formula. Points of interest connected with the uses, constitution, and chemistry of the various extracts were treated of as they arose.

Leauros The results of the examination of a supply of this plant, popularly known as "motherwort," handed to Mr. W. A. H. Naylor some time ago by Mr. E. M. Holmes, who had grown it, were next given in brief. The fresh herb having been pressed, 20 per cent. of rectified spirit was added to the juice obtained, as a temporary preservative, and, after some preliminary tests, the "succus" was evaporated over a water-bath to a soft extract. This extract was then treated with absolute alcohol, which left a residue partially soluble in water. The
matter soluble in alcohol was successively treated
with ether, chloroform, etc.; the residue soluble
in water and the insoluble residue were separately
examined; and, finally, the marc left after express-
ing the juice was carefully investigated as to its
constituents. The total results thus far obtained
may be stated as follows:—Dinitre—potassium
chloride, calcium phosphate, citric, tartaric, and
malic acids; proximate—bitter principle, hard
resin soluble in chloroform and insoluble in ether,
soft resin soluble in chloroform and ether, alka-
loidal substance, potassium salt of an organic acid,
fixed oil, wax soluble in petroleum ether, wax in-
soluble in petroleum ether, extractive soluble in
alcohol and water, two extractives soluble in water
only. This investigation serves as a useful illus-
tration of the great amount of work required to
determine the constituents of a single plant. The
motherwort is not indigenous to this country,
though it occurs in "hedges and waste places,
England, Scotland, Ireland, Channel Islands, rare."
Its distribution, according to Hooper, is "Europe,
N. and W. Asia, Himalaya; introd. in N.
America." The herb is used for medicinal pur-
poses in the United States, Maibur describing it
as containing volatile oil and a bitter principle, and
possessing pectoral, tonic, and stimulant prop-
erties. It is generally administered in the form
of an infusion, the dose being equivalent to 2 to 4
Gm. of the herb. A note on L. cardiaca, con-
tributed at the last moment by Mr. E. M. Holmes,
was considered at the same time as Mr. Nayler's
paper, and gave a brief historical account of the
plant as a medicinal agent.

Conditions of Pepparin studying the behaviour of papain as
Digestion, a digestive agent, Dr. S. Ridgeway, in
the next paper, described some results obtained which
seemed to him to clear up certain points that
previously appeared doubtful. The pure ferment
has not yet been isolated, and at present it is,
according to Dr. Ridgeway, impossible to
determine the amount in commercial samples, so that the value of any given specimen
as an aid to digestion "can only be measured in
terms of its relative activity to different brands of
pepsin." It is hardly necessary, however, to
remind our readers that the fallacy of tests of this
kind has been repeatedly exposed in the Journal
and elsewhere. The two fermenters have but little in
common in their properties, and if it be true, as
recently suggested, that much commercial papain
contains pepsin, what slight resemblance has been
apparent may have been due to ignorance of the
nature of the material experimented with. The
experiments described by Dr. Ridgeway dealt with
the influence of temperature, the rate and the amount
of ferment, water, or other substances present, on
the rate of digestion. The action of papain in
acid, alkaline, and neutral solutions was then
considered. Compared with pepsin under identical
conditions, papain seemed to give the better results
with meat fibrin, but with regard to egg albumin
its digestive power appeared intermediate between
that of the two pepsins examined.

Cocoa-nut Stearin. Subsequently, the value of cocoa-nut
steain as a basis for suppositories and
Suppositories pessaries was considered by Mr. C. J.
S. Thompson. In a paper read before the Phar-
maceutical Society in 1866 (see Ph. J., xxv., 544)
Brady referred to this stearin as being an inexpen-
sive substitute for thobroma butter, and he stated
that the following mixture "seems to keep
unchanged for any reasonable length of time, and
leaves little to be desired as a basis for pessaries":
—Cocoa-nut stearin, 9 oz.; lard, 1 oz.; oil of pimento,
20 minims. The lard was introduced partly as a
tempering medium, and partly "to facilitate the
proper division and admixture of the medicinal
substance before adding to the melted stearin."
The oil of pimento, of course, served as an an-
septic and prevented rancidity. Mr. Thomson
finds, however, that this base is too soft, as it
melts at 82° F. A formula giving satisfactory
results in his hands is:—"Cocoa-nut stearin, 4 oz.
white wax, 340 grm. Melt together with gentle heat
over a water-bath." The melting point of the
product is 88° F., and it becomes solid at 64° F.
The mixture is said to form an admirable
suppository base for belladonna, hamamelin, boric
acid, and many other combinations. When desired,
the melting point is easily lowered by using less
wax. The base mixes well with vegetable extracts,
does not go soft on keeping nor become rancid in
contact with metallic salts, and it cools more rapidly
than thobroma butter, so that suppositories can
be taken from the mould in about ten minutes.

Phosphorus. The method recommended by Mr.
in Phisters. R. H. Parker, in the following
note, for preparing phosphorus pills con-
sists in dissolving sufficient phosphorus
for twenty-four pills in carbon disulphide,
30 minims, pouring the solution upon liquorice pow-
der, 34 grains, in a pill mortar, and stirring uniformly
within the smallest possible space, by means of a
spatula, until the solvent is nearly evaporated.
As soon as the mixture becomes nearly solid, but
whilst still moist, sufficient syrup is added, together
with glycerin, 4 minims, and tragacanth powder,
2 grains, to form a soft pill mass, which is incor-
porated quickly until homogeneous. Any other
ingredients may then be added and the mass
divided into twenty-four pills, which need not be
coated, and keep without material loss or oxidation.
For determining the amount of free phosphorus
the method adopted was to extract with carbon
disulphide, oxidize to phosphoric acid, and titrate
with standardized uranium acetate solution.
In view of the possible advent of official an imperial pharmacopoeia, Mr. 
remedies. Joseph Ince asked in the next 
paper that as new official remedies are 
adopted the latinised names applied to them 
should follow the ordinary rules of declension, as 
commonly known and accepted. His paper, which 
was full of examples, cannot profitably be con 
dense, but our readers will find it well worthy of 
attention when it is published in the Journal later. 
It may be stated, however, that no novelty in 
omenclature was advocated, but only the 
 systematic adoption of known rules in grammar to 
impose new requirements, the present condition of 
affairs being said to reflect on the scholarship of the 
lay and embarrass the prescriber, who, "owing to 
the technical arrangement of a prescription, has to 
frame a terminology with declensions of his own."

A historical account of the intro 
duction of medicinal rhubarb into 
England and its subsequent cultivation 
was given in a paper by Mr. 
Richard Usker, who pointed out that the 
effects of seedling cultivation of this plant 
are injurious. The inferior quality of the 
English rhubarb root of a few years ago was stated 
to be due to this cause. Since, however, 
propagation from offsets has been exclusively resorted 
to, the plant has been restored to its primitive form of 
development and the product greatly improved, 
and prejudices against English rhubarb root are 
rapidly disappearing. With regard to henbane, 
Mr. Usker suggested that the plants should be 
classified in the order of their value into (1) 
biennial henbane of second year’s growth; (2) 
biennial henbane of first year’s growth; (3) 
British annual henbane; and (4) German 
henbane. It is now found possible, after a long 
and careful study of its cultivation, to preserve the 
first from the attacks of insects to which it is 
oridually subject, and thus loss of material and 
temptation to substitute inferior varieties are pre 
vented.

The remaining papers were taken as read:—

The effect of the use of various 
estimates on the tinctura ergotis ammoniaca should be 
become cloudy on adding a fluid drachm to two 
ounces of water, while another remained clear 
under identical conditions. After performing a 
number of experiments he concluded that the fixed 
salt of the ergot and the soap formed from it by the 
Action of the spt. ammon. aromat. remove part 
of the essential oils and prevent the remainder from 
being dissolved. Consequently, the resulting tinc 
ture remains clear when mixed with water, although 
the menstruum with which it is prepared will not. 
This result is only produced, however, when the tinc 
ture is prepared by percolation and the whole of the 
menstruum is passed through the ergot. If pre 
pared by maceration and any deficiency in the 
quantity of the product is made up by adding fresh 
spt. ammon. aromat., a tincture is produced which 
will cause more or less cloudiness when mixed with 
water, according to the amount of the spirit so 
added.

The paper by Mr. B. S. Proctor gave an account of numerous observa 
tions and experiments which he had 
made during his pharmaceutical experience. The 
work originated with the desire to know whether the 
trade custom of trimming rhubarb was benefi 
cial or otherwise. Experiments were detailed 
showing that soluble matters contained in water 
with which a porous body is saturated accumulated 
at the surface as the body becomes dry by evapora 
tion, and that this migration of matter does not take place during the drying of a hydrated 
colloid. This action was supposed to account for a 
greater richness in extract in the exterior of the 
root than in the interior which was observed in the 
early experiments, but not found by subsequent 
experiments to be uniformly the case. The 
odorous principle of the root was found capable of 
being extracted by percolation with chloroform, 
without detracting from the medicinal value of the 
powder; but it was also found that the deodorated 
powder acquired small again, apparently by the 
action of air and moisture. After some comments 
upon Dr. C. A. Brown’s analysis of rhubarb and the 
solubility of the different constituents of the root, 
Mr. Proctor pointed out that a simple method of 
assaying this drug suitable for the use of pharma 
cists was not yet in prospect. The presence of 
chrysophanic acid in both dried and fresh 
roots was shown, and that when the 
powder has been exhausted of this constituent by 
percolation with benzol, a further development of 
the acid takes place on submitting the exhausted 
powder to the action of air, water, and caustic potash. Fat was shown to be a natural constituent 
of the root, though in no case was it found in so 
large proportion as was formerly the case in the 
commercial powder. A few suggestions were made 
regarding some pharmaceutical preparations, and 
the paper concluded by indicating several points 
still requiring further investigation.

Soap Basis The advantages possessed by lini 
ment of potassium iodide over the 
other B.P. liniments induced Mr. E. 
W. Lucas to consider whether a similar basis might 
not with advantage be adapted to the latter. It 
is therefore suggested that a useful preparation 
for the purpose may be made by dissolving curd 
soap reduced to fine shreds, 4 ozs., and soft soap, 
1 oz., in distilled water, 16 ozs., by the aid of gentle 
heat, and then adding glycerin, 2 fl. ozs., and 
sufficient distilled water to make the strained
product weigh a pound and a half. The product is poured into a suitable vessel and allowed to solidify. Taking this as a basis, formulae, which will be published in the Journal later, were given for the limen of eucalyptus, belladonna, camphor (compound), iodine, opium, potassium iodide, soap, and turpentine. It is anticipated that such limen will be more readily absorbed by the skin than the ordinary preparations, while they are more cleanly and easy of application, as well as more free from risk of confusion with medicines for internal use.

Tincture of Iodine. The theoretical composition of a tincture of iodine, according to Mr. J. F. Liveris, is iodine, 2-47 Gm., potassium iodide, 2-47 Gm., absolute alcohol, 69-56 Gm., and water, 13-25 Gm., or in all 87-75 Gm., in each 100 C.c., and its specific gravity should therefore be 0-8775. Suggestions were made by him to vary the instructions of the B.P. regarding the method of taking the specific gravity and determining the amount of iodine present. Details were also given regarding both the direct and indirect determination of these and other ingredients of the tincture, and tabular statements were submitted to show the results of the analysis of a number of samples.

Calibration of Pipettes. In a paper by Mr. J. F. Liveris, the precautions to be taken before calibrating pipettes were described and the results of a number of determinations were given. It was noted, by the way, that since the grain measure of the British Pharmacopoeia is required to be the volume of one grain of water at 16° C., and the fluid ounce is the volume of 437-5 grains of water at 16° C., the latter will measure 437-57 grain measures. The errors in some British pipettes were stated in tabular form, as well as the mean results of the examination of a series of metric pipettes, and a method of approximate correction was described.

Essence of Lemon. The object of Mr. A. A. Barrett’s paper was, in his own words, “to draw attention to the absolute worthlessness of the tests in common use for the examination of essence of lemon.” Rubbing the oil on the hand and smelling it and the use of the polarimeter were both condemned, though it was acknowledged that the latter test had done good work, and “prepared the way for the acceptance of a really scientific test” which, however, remains “to be evolved during the next year or two.” Mr. Barrett has found that genuine essence of lemon may differ in its optical activity between +57° and +72°, whilst the addition of per cent. of raw turpentine makes a difference of four or five degrees only in the rotation. The refractometer was also condemned as being of no use in the case of essence of lemon, and the specific gravity test was described as very variable in its results. Delicate and reliable tests for mineral oil are solution in alcohol and evaporation from paper. A number of empirical tests in use were said to be not worthy of attention, and the direction in which progress is now to be looked for is chemical rather than physical. Some one constituent present in constant proportion in the oil should be selected, and the value of the specimen examined should be based on the determination of this.

Extract of Indian Hemp obtained from various sources, Indian Hemp, and comparisons of them with extracts of English origin, were contributed by Mr. David Hooper, who, in his recent position as analyst to the Indian Hemp Drugs Commission, has enjoyed exceptional opportunities of gathering information concerning the composition of Indian hemp. His paper had particular reference to the pharmacopoeial extract, and dealt first with its preparation from different varieties of “ganja,” next with its composition, and finally with the examination of commercial extracts. In conclusion, it was stated that many dealers in India renew their stock of “ganja” annually, and always consider the drug worthless after being kept three years. It was suggested, therefore, that the loss of reputation of the extract in England may have been due to failure of action owing to the decomposition of the active principle present.

Election of Committee. The whole of the papers having formulary been disposed of, Mr. Lloyd Committee. Williams then proposed that the members of the Formulary Committee should be reappointed. This was seconded by Mr. Linford, and carried unanimously, and Mr. Martin, returned thanks on behalf of the elected members.

Bell and Hille’s Fund Bell and Hille’s Fund was acknowledged by Mr. Drueck, who stated that the volumes would be placed in the local municipal library until such time as a pharmaceutical association should be formed at Oxford.

Place of Meeting. An invitation being received from the chemists of Bournemouth, at the hands of Messrs. Bridge and Toone, for the Conference to assemble there next year, it was unanimously resolved, on the motion of Mr. Gerrard, seconded by Mr. Ward, and supported by the President, to accept it.

Election of Officers. The election of officers was then proceeded with, and resulted as follows:

President—N. H. Martin, Newcastle-on-Tyne.
Vice- Presidents—M. Cartelgé, London; J. Laidlaw Ewing, Edinburgh; W. Hayes, Dublin; J. A. Toone, Bournemouth.
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS.

August 4, 1894.

Local Secretary—Stewart Hardwick, Bournemouth.

Votes Finally, on the motion of Mr. Groves, seconded by Mr. Jones, a hearty vote of thanks was awarded to the governing body of Christ Church for the use of the college hall for the reception and conversations; on the motion of Mr. Cartwright, seconded by Mr. J. Ince, cordial thanks were accorded the authorities of New College for enabling the garden party to be held in their grounds; and on the motion of Mr. Atkins, seconded by Mr. John Moss, the Master and Fellows of Balliol College were similarly thanked for lending their hall for holding the sessions of Conference. The local committee, the President, and the Honorary General Secretaries of the Conference were also thanked for their services, and the proceedings then terminated.

An illustrated record of the proceedings in connection with the social side of the Conference meeting is embodied in the form of an illustrated supplement to the present issue of the Journal. Allusion has already been made to the gratifying success which has attended the efforts the local committee to render this visit to Oxford a memorable and enjoyable one, and fairly favourable state of the weather, on the whole, tended much to assist in this direction, since so many of the principal charms of Oxford are found out of doors. The usual photograph was taken on Wednesday in front of Balliol Hall, and should prove an attractive memento of the beautiful surroundings. The conversations on Monday, garden party on Tuesday, smoking concert on Wednesday, and river excursion on Thursday were all highly successful, and will doubtless leave many pleasant recollections in the minds of all who were present.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

On Wednesday next, August 8, the British Association will assemble at Oxford for the fourth time. It first met there in the second year of its existence, under the presidency of the Rev. W. Buckland, in 1832. The next meeting in the famous old university city took place in 1874, when Sir Robert grill was president, and the third in 1880, when Huxley, Owen, and others gave zest to the proceedings during the discussions on the revolutionary doctrines embodied in the then recently published "Origin of Species." The Chancellor of the University of Oxford, the Marquis of Salisbury, K.G., will preside over the meeting on the present occasion, and it is anticipated that the attendance will probably reach two thousand. The presidential address will be delivered in the Sheldonian theatre on Wednesday evening, and is expected to deal with some of the great unsolved problems in science. The following are the presidents of the different sections:—Mathematical and Physical Science, Professor A. W. Röcker, F.R.S.; Chemistry and Mineralogy, Professor H. B. Dixon, F.R.S.; Geology, Mr. L. Fletcher, F.R.S.; Biology, Professor I. B. Balfour, F.R.S.; Geography, Captain W. J. L. Wharton, F.R.S.; Economic Science and Statistics, Professor C. F. Bastable; Mechanical Science, Professor A. B. W. Kennedy, F.R.S.; Anthropology, Sir W. H. Flower, F.R.S.; and Physiology, Professor E. A. Schäffer, F.R.S. Soirées will be held on August 9 and 14, and the concluding meeting on Wednesday, August 15.

THE OXFORD HANDBOOK.

The illustrated handbook on "Oxford and its University" proved an unqualified success, its reception by the members of Conference appearing to fully justify the anticipation that it would add somewhat to the interest of the Oxford meeting. Sir Henry Acland and the Mayor of Oxford both referred to the book in highly appreciative terms, as did also the President, Mr. Martin, at the close of the proceedings on Wednesday, when he quoted with approval, the concluding words of the preface, which stated that the whole of the work in connection with the work had been done in the hope of adding to the success of the Oxford meeting, and further cementing the bonds which unite the British Pharmaceutical Conference with the Pharmaceutical Society of Great Britain and its official organ." Readers who have applied for copies will be supplied in the course of a few days.

MEDICAL GRADUATION.

It is with much pleasure we note that, in the list of those upon whom the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.) were conferred at Aberdeen University on Friday, July 27, the name appears of Robert Johnston, son of Mr. John Johnston, Member of Council of the Pharmaceutical Society.

DR. C. R. A. WRIGHT.

The death of Dr. C. R. A. Wright, lecturer on chemistry at St. Mary's Hospital, will be a source of surprise as well as regret to many readers of this Journal, to whom he was known by his investigations of opium and ancone alkaloids, and as a frequent attendant at pharmaceutical gatherings.

SCIENCE SCHOLARSHIPS.

We are informed that Daniel Hanbury White, apprentice with Messrs. Giles, Schacht and Co., of Clifton, has recently obtained a John Stewart Scholarship at University College, Bristol. It is to be hoped that this success may foreshadow a career honourable to the memory of the gifted man whose name the scholar bears.
Transactions of the Pharmaceutical Society of Great Britain.

SCHOOL OF PHARMACY PRIZES EXAMINATION QUESTIONS.
Session 1893-94.

SESSIONAL EXAMINATION FOR A SILVER MEDAL AND THREE CERTIFICATES OF HONOUR.

CHEMISTRY.
Professor Dunstan.
Thursday, July 26.—Hours from 10 to 1.

1. Explain precisely what is meant by “reduction” and “oxidation.” Classify the following substances into reducing and oxidising agents, giving examples of their action—hydrogen sulphide, nitric acid, nitrous acid, hydrogen peroxide, hydrogen lodide, hydroxylamine and chromic acid.

2. Describe in detail two distinct methods of separating pure silver from an alloy of silver and copper. How are the following silver and copper compounds prepared, and what are their chief properties—silver nitrite, cuprous chloride, cuprous oxide, cuprous hydroxide, and silver sulphate.

3. The same current is passed for the same time through solutions of the following compounds—hydrogen chloride, silver sulphate, copper sulphate, potassium chloride, lead nitrate. Describe what happens, and state the relative amounts of the products formed at each electrode.

4. Describe the construction of a polariscope, and explain how it is used. What has been ascertained with reference to the relation between the chemical constitution of a substance and the action of a solution of it on the polarised ray?

SESSIONAL EXAMINATION FOR A SILVER MEDAL AND THREE CERTIFICATES OF HONOUR.

CHEMISTRY.
Professor Dunstan.
Thursday, July 26.—Hours from 2 to 5.

1. Trace the similarities and differences between the following pairs of organic compounds:—benzolic acid and acetic acid; ethylamine and aniline; phenol and alcohol; acetic aldehyde and benzoic aldehyde.

2. Give an account of the chief differences between aldehydes and ketones. Classify the following compounds, giving your reason in each case:—acetone, camphor, dextrose, levulose, oil of meadow sweet, oil of bitter almonds.

3. Describe, with equations, the action of chlorine on ethyl alcohol and on acetic aldehyde. What are the chief properties of the products?

4. Explain the relation of the following vegetable alkaloids to pyridine:—Piperine, atropine, nicotine, and cocaine.

QUESTIONS FOR THE TERMINAL EXAMINATION IN THE CLASS OF PRACTICAL CHEMISTRY.
Professor Attfield.
Friday, July 27.—Hours from 10 to 1 and 2 to 5.
Books and Memoranda permitted. Manipulation as well as results will be scrutinised.

1. Ascertain the specific gravity and yield of nitric oxide of the sample of “Spirit of Nitrous Ether,” and give the results in figures.

2. What substances are present in the fluid “A”?

3. Name the substances “X,” “Y,” “Z.”

4. A single poison is present in “The Flour.” State its name.

MATERIA MEDICA.

PRACTICAL HISTOLOGY.
SESSIONAL EXAMINATION FOR A SILVER MEDAL.
Saturday, July 28.—Hours from 10 to 1.
Professor Henry G. Greenish.

1. By what reagents would you distinguish—
(a) Lignified and
(b) Suberized cell-walls from each other and from pure cellulose! How would you identify
(c) Calcium carbonate,
(d) Mucoilage,
(e) Inulin,
(f) Oil, microchemically?

2. Examine and describe the structure of the drug submitted to you (oak bark); cut such sections and apply such reagents as you consider necessary; illustrate your description with sketches, and leave a transverse section mounted in glycerin for inspection.

Scottish Transactions

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.
The fifth and last botanical excursion of the season took place on Wednesday, July 18, to Inversae, leaving Waverley Station by train at 8.15 p.m. Arrived at Inversae, the company walked down the valley of the Esk to Musselburgh, and returned to town by train at 10.50 p.m. One notable feature in the flora of the valley was the great profusion of Scrophularia nodosa. Some fine specimens of Pyrethrum pardinum with yellow foliage were also met with, apparently an escape from some garden higher up the river. The excursion was conducted by Mr. Alexander Sutherland, President.
The British Pharmaceutical Conference.

MEETING AT OXFORD.

The business of the thirty-first annual meeting of the Conference commenced on Tuesday, July 31, in the Hall of Balliol, the chair being taken by the President, Dr. N. H. Martin, F. L. S., F. R. M. S. He was supported by the Mayor of Oxford, the Master of Balliol, and Sir Henry Acland, Bart., K. C. B.

The Master of Balliol (Dr. Edward Caird) opened the proceedings by welcoming the Conference to the Hall of Balliol, which, he said, could not be put to better use than to serve as the meeting place of such a course as this, in which those engaged on any particular subject met together to exchange their views, to compare notes, and so to advance the subject in which they were interested.

The Mayor of Oxford next, in the name of the city, extended a welcome to the Conference to the ancient city, in which during the last quarter of a century more than the elements of science, chemistry and pharmacy; he saw the value of character, for he would undertake to say that Peter Squire, as far as his knowledge went, never had anything in his place, for he believed to be of the very best; and he had seen Mr. Bullock throw away a whole evaporating dish of ammonio-citrate of iron which he thought had not been properly made. Beyond education and science, personal character was of the highest importance, and should always be so regarded.

Sir Henry Acland, Bart., said he was very grateful for the opportunity of being present at this Conference. He was not officially deputed by the authorities of the University to welcome them, but it was his duty to do so, on the part of the University, so far as he might, but beyond that, on behalf of the nation and of science. The President and many present were aware that the whole question of science, particularly medical science, and, along with it the question of scientific pharmacy, was undergoing a change and going through a process of enlargement which the world had never before seen. This depended on various causes—on the progress of biology, and on the broad views taken of the whole nature of life upon our planet—and attention was now being given throughout the world not so much to the treatment of disease as to the prevention of it. This was a point which he might not have mentioned but for the fact that being clearly mentioned in the 'Extra Pharmacopoeia,' and as reference was made to the fact that already in this country pharmacists were considering the relation of bacteriological studies to the treatment of disease. This question, looking at pharmacy from the artistic rather than the scientific side, raised the question how the line was to be drawn between the preparation of those things which would be required in the future from the few old-fashioned remedies which he remembered in his youth. To pursue this subject further would take too long, but he hoped to hear something upon it in the course of the meeting, and he thought that this was not only a national question for England, but for the whole world, as was shown by the congresses held, or being held, at Chicago, Japan, and Baden-Baden for the prevention of disease.

As he said to the Pharmaceutical Society, in London several years ago, he desired to bring the pharmacists to the public. When he was at the commencement of his education—he hoped he had not yet completed it—at a great London medical school, in 1840, there was no popular teaching of pharmacy, and he met Peter Squire, who would not take pupils, made an exception in his case, and invited him to his house from cellar to attic, so that he had the opportunity of seeing every process that went on in that establishment. The following year he found there was no teaching of practical chemistry, and another member of the pharmaceutical body, Mr. Lloyd Bullock, the friend of Liebig, and the translator of Fresenius, in the little laboratory at the back of what was called his shop, worked with him and he was instructed, scolded and taught in a way that could not be surpassed. He had a life-long affection for those two men and a deep feeling of gratitude, which it was his bounden duty, as well as his pleasure, to acknowledge. He learned from those two men a great deal more than the elements of science, pharmacy and chemistry; he saw the value of character, for he would undertake to say that Peter Squire, as far as his knowledge went, never had anything in his place, but he believed to be of the very best; and he had seen Mr. Bullock throw away a whole evaporating dish of ammonio-citrate of iron which he thought had not been properly made. Beyond education and science, personal character was of the highest importance, and should always be so regarded.

The President, in the name of the Conference, thanked the Master of Balliol, the Mayor, and Sir H. Acland for the welcome they had extended. It was a great pleasure to be so kindly received by a man who was known to be the rejuvenator or re-creator of the teaching of natural science in connection with the University, seeing that natural science was the foundation of pharmacy. He hoped what had been said by Sir H. Acland would sink into their minds, and he should like to emphasise one word he had used on those who had to do with the teaching of young men. Sir Henry said that his own early education included scolding, and he feared that in the present day there was far too much petting and bribing and hardly enough scolding. He entirely agreed with what he said about bacteriology, and in connection with one of the papers about to be read, he intended to have said, what had now been said in effect by so much a higher authority, that the chemist and druggist of the future would have to be a man who could not only take tincture of rhubarb, but could make a culture of scarlet fever when it was required to treat a scarlet fever case. He must be a scientist and be able to prepare and guarantee all the products he handed to the physician for the treatment of disease.

The President then delivered his address.

The President's Address.

Gentlemen,—At the outset of my address I desire to conform to a custom which I think we do well to honour, and that is to express to you my sense of the distinction which you have conferred upon me by electing me to be your President. To be thought of my confreres to be fitted in some small degree to stand in the place which has been occupied and adorned by such distinguished men and pharmacists as Deane, Hanbury, Stoddart, Brady, Redwood, and others who have occupied this chair, is a sufficient cause for modesty and honourable self-respect, and I should not be human if I did not appreciate that honour, and feel proud of the dignity. I do not propose to occupy your time by expressions about my own unworthiness, for although the fact, and the causes of it, are better known to me than they can possibly be to you, the attempt to put them into words would miss that ring of true sincerity which I have tried to make the touchstone of my life. I prefer to accept your decision in silence as to my own shortcomings, and to tell you that since your choice has fallen on me, I have done my best to make my unworthiness more worthy of your acceptance.
As you are all aware, we are indebted to the courteous invitation of the pharmacists of this city and neighbourhood for our meeting here to-day, and I congratulate the Conference upon the opportunity of assembling for the first time in its history in this ancient university city.

Oxford is as fresh to me as I have no doubt it is to many of you, but we shall every one of us share an Englishman's just pride in the renown of this historic seat of learning. Perhaps to some of us it was a dream and a hope of our early days that our own education would embrace an Oxford or Cambridge career, but such dream may have been rudely dispelled by the force of circumstances, and the ideal of education which we thought could have been obtained here, by the culture of surroundings, we have only been able to seek after by much plodding and gleaning in outside fields. If I were free to occupy your time with thoughts other than those connected with pharmacy, what a fruitful source of inspiration this place would be. The beauty and the history of its buildings, the men who have walked these streets and lingered in these ancient halls and colleges, and who have gone out from here to influence so profoundly the whole history of the world, would indeed furnish any audience of Englishmen with food for profitable meditation. In our thoughts about Oxford most of us will have connected it with classical and mathematical studies, and with the remembrance that here have been trained some of the deep thinkers in the realms of philosophy, of theology, and of history. To us as pharmacists, however, and as workers in the domain of natural history and science, the Oxford Museum cannot fail to be an object of the deepest interest, and while I hope you will take away from Oxford many delightful mental pictures of art, of architecture, and of natural beauty, I would commend the museum and all that pertains to it to your most thoughtful attention and study. I may not linger here, but I should like to point out the wide difference which exists between the Oxford Museum and our ordinary conception—and, I am afraid I must add, our experience—of museums in general. In the dictionary you will find a museum defined as a repository of interesting objects, and in too many cases in this country they are "repositories," and nothing more. Here, however, you will find the museum is not the grave of curious and interesting specimens, but is the centre of a vital contact with nature and science. You will find the museum proper surrounded by suitable buildings and by every provision for education, for study, and for research in the various branches of natural science, and the objects in the museum are used to fulfill their proper function in illustrating the lectures of the professors and enriching the knowledge of the students. In my own city we have a natural history museum, rich in specimens, and we have colleges of science and of medicine, under wholly different management, at no great distance, and every lover of scientific truth in the North must regret with me that the dry bones of the museum are not vivified by contact with the living teachers and students of science. It is an evidence of the clear judgment and breadth of view which university life and training imparts, that here in Oxford the museum has not been conceived in the spirit of the miser, to collect and to hoard, but the collections are used to communicate pure streams of accurate knowledge to all who will come and drink at this fountain. You will see that medicine forms no inconsiderable part of the teaching associated with the museum, but according to Sir Henry Acland "the function of the Oxford Museum towards medicine is to train good scientific observers and thinkers to become observers and thinkers in pathological and therapeutic and preventive processes." I trust it is not a mere dream to hope that some day pharmacists will be found here amongst the students laying the foundation to become "good scientific observers and thinkers."

The subject of my address will be medicine and pharmacy, and however well the story of these may have been told by my predecessors, I am by virtue of my position under the necessity of keeping to the beaten track, and I have no desire even to shrink the responsibility. I purpose to take full advantage of my position as your President and to speak to you as cathedra. I do not expect that you who hear me, or that those who may afterwards read what I shall say, will agree with all that I express, but of one thing I beg to assure you, my views upon this subject have not been hastily adopted, and they are not lightly held. They are the outcome of more than thirty years of a wide contact with pharmacy and medicine, and of loving service to pharmacy, which during that period has been to me not alone a source of income, but the means of bringing me into contact with a large proportion of the purest pleasures that have come into my life.

It is not possible to exaggerate the importance of medicine and pharmacy in the body politic. The duty of healing and caring for the sick should call forth, in every right-minded man with the spirit of true nobility in his soul, feelings of the highest charity and honour, and he is surely one of the most miserable of human beings who is satisfied to pursue these callings for mere gain, and to measure the success of failure of his life devoted to medicine by a money standard.

Our own daily work and our thoughts and actions are more intimately connected with pharmacy, but we meet medicine on the common ground of drugs, their preparation and application in the treatment of diseases. Medicine in the persons of those who practise it, and in the pages of its representative journals, does not hesitate to criticise and even to castigate pharmacy, and I propose to extend my remarks to revealing shortcomings in the practice of medicine.

Let us turn first, however, to pharmacy, and ask the question whether in its own special domain in condition is satisfactory, and, if not, what is the cause of this, and what suggestions for its improvement can be offered. The Pharmaceutical Society has had an existence of over fifty years, and we have had a compulsory Act of Parliament for twenty-six years. In that period advances have been made which are obvious, and I need not recount them any more.
I need place before you confirmatory evidence of the fact that the majority of those who are on the Register of Chemists and Druggists are dissatisfied with the actual practice of pharmacy to-day. Complaints are loud and deep against the Pharmaceutical Society because it does not bring about an improved condition of things, but in no case have I seen the confession by any large section of men on the Register that they have failed to realize the privileged position in which they were placed by the Act of 1858, and that they have neglected to conform to the keynote and true spirit of that Act, which was—education. I think you will agree with me that the greatest evil from which pharmacy is suffering to-day—unbridled and dishonest competition in prices—is mainly due to the enormous extent to which the use of proprietary medicines has increased, and to the fact that this has played the role of introducing grocers, limited companies, and other unqualified and unregistered individuals and bodies to assist in their distribution, and has tempted them to add to their sale a large number of the drugs in common use, and finally has evolved that monstrosity of the nineteenth century, the "company pharmacist." Who is to blame for this? Surely not the Pharmaceutical Society, for whatever individuals may have done, the whole spirit and teaching of the Society is in direct opposition to pharmacists becoming the medium of distributing articles about which they have absolutely no personal knowledge, and about which they can give neither to physician nor to patient any information based upon their scientific training and experience as pharmacists.

No, it is not the Pharmaceutical Society which is to blame, but it is the men on the register who, in the past, in their several localities, by their endorsement of the falsehoods of these advertising quacks, have created on the part of the public this enormous and unhealthy demand for proprietary medicines, and have brought this Nemesis upon pharmacy.

Here I must mention a further development of the proprietary medicine system which has recently taken place, and which is fraught with far more peril to the existence of pharmacy than the proprietaryaries for domestic use, and in this both medicine and pharmacy have been ensnared by the wily commercial adventurer. In various guises, and by persistently advertising claims to improvements in pharmacy, men, seeking gold, have induced medicine and pharmacy to become their tools to enable them to reach the million. There are two chief methods by which this has been accomplished; one is by the registration of a word for some particular form in which drugs may be administered, the other is by the invention of names ("proprietary names") I see one medical writer euphemistically calls them) which are used as blinds to suggest some original or added virtue, for compounds, the properties of the ingredients of which are perfectly well known. These enterprises would have met but with poor success if medical men and the medical journals had been true to themselves and to their own teaching. You can imagine the incredulous smile with which an accomplished physician would receive the assertion of some antiquated herbalist that he knew a weed which was an universal cure, but when such a weed is made the basis and furnishes the name to a compound manufactured by an enterprising company, and is presented to him with a sample bottle, a pamphlet bristling with comments from medical journals and testimonials, under the name of Liquor Curative Co., the amiable physician falls into the trap, and his next patient is dosed with the latest improvement in modern pharmacy—"Liq. Cure-all-ine Co." The medical journals, however, in their advertising columns and in their literary pages are the strongest supporters of these quackeries. I do not suggest, and it would be preposterous to suppose that the learned and versatile editor of the British Medical Journal would listen to an appeal of this sort.

"Dear Sir,—Advertising as we do in your valuable and esteemed medium, and being likely to continue the same in the future on an extensive and liberal scale, we shall esteem it a favour if you will kindly give us at an early date the superadded benefit of a free editorial, the substance of which we beg respectfully to submit herewith.—We are, dear Sir, yours faithfully, Bunkum, Quack and Co." There cannot be the slightest doubt of the reception which such a letter and such an appeal would get at the hands of the editors and proprietors of our leading medical journals. But let B. Q. and Co. approach the matter by advertising on an extensive scale in the Journal, and then send samples for analysis and report, and if we read nothing stronger it will at least come out something after the following:

Skinnaire.

"It is claimed that the substance contains the active principles of skin in the proportion of twenty grains to the pound. We have put these claims to the test as far as possible, and we are satisfied that they are practically justifiable, but we are not able to endorse all that the discoverer claims for the preparation, although there is no reason to doubt his statements.

To the stern logic of science, this is lukewarm enough in all conscience, but the estate advertiser is satisfied. He probably did not expect what was impossible, any definite analysis and report, but he knows, cautiously worded and valueless as the paragraph is as to the merits of skinnaire, he has only to quote the paragraph and add the magic words of the title of the journal, and the commercial result to him will be increased a hundredfold. I venture to assert that such notices are absolutely unworthy of the highest and best traditions of medical journalism, and they are the ruin of scientific medicine and pharmacy. I could give you many illustrations, but forbear to weary you. I believe the Americans were the first to make the discovery that the doctor might be made a cheap and efficient means of advertising, although the Germans have not unsuccessfully cultivated the same field, and it is to this source that we owe the experience that the consulting rooms of the medical practitioner are deluged with "physician's samples" of the most arrant quackery the world has ever seen. When will English medicine have the courage to purge itself of this corruption?

It will be interesting I think to enquire into the
possible reasons why medical men have so readily fallen into these traps, and I think one great and most important cause has been the neglect to give the medical student adequate training in the knowledge of the properties and uses of drugs. Since the abolition of apprenticeship to a general practitioner, which used to precede in medical education the scientific course which in those days was called "walking the hospitals," the tendency has been for more and more of the medical student's time to be taken up with the abstract sciences which are the basis of his art, and the practical side of being able to treat and cure disease by the intelligent use of medicines has been very largely neglected. The result is that instead of the diagnosis and the cure going together in intelligent connection, they have been separated from each other, and it has happened to a brilliant and successful student of our medical colleges that, after having made the most exact diagnosis, the limit of his powers has been reached, and his grim function has been to watch the patient die, and to be able to predict the precise pathological changes which would be revealed at the necropsy. Another great cause, which I am sure has had a wider influence in discreditizing the use of drugs in the treatment of disease than we can have any idea of, is the tender system under which many hospitals and infirmaries—where young men get their first lessons—are supplied with drugs. It is no secret that large quantities of inferior and almost useless drugs are year by year placed on the market, and I do not think it is in the least unfair or unjust to infer that these must largely find their way into the institutions and into the possession of those who make the price their sole criterion of value. It follows, quite in logical sequence, that teachers and taught are influenced by the variable and uncertain results obtained, and that sometimes in despair and sometimes in contempt there is produced a lack of faith in drugs as instruments of healing. I do not underrate in the smallest degree the importance of the medical student acquiring sound and extensive knowledge of physiology, pathology, and so forth; they are absolutely essential subjects, and I would not belittle the triumphs and advances which recent years have seen in these directions, but the subject of profound importance to the patient is to be cured. The exorbitant claims sometimes advanced on behalf of such subjects as physiology, pathology, and chemistry have been fraught with no little danger to the art and practice of medicine, and it has happened that many a general practitioner, who in the realm of physical danger would be a hero, has been deterred by a sneer or an assumption of superiority on the part of some specialist from contending for the reality of the knowledge which is the result of his own life-long experience in the use of drugs, and the knowledge itself has, in some cases, been lost to the service of medicine in its combat with disease.

To return to pharmacy, the small amount of relative success which has resulted from the work of the Pharmaceutical Society, is in my opinion largely due to the grave mistake which was made in the fifth clause of the Pharmacy Act, 1868. By that clause it was decided to place on the register, without examination and without fee, all who claimed to have been in business as chemists and druggists prior to December 31, 1868. If an adequate fee for the privilege of being registered had been imposed, I think it would have had the effect of considerably reducing the number of those who desired to be placed on the register from purely trade motives, and it would have created in the minds of those who were registered a wholesome feeling of respect for the body to which it had cost something to become affiliated. The result was that a large number of penurious were placed upon the register who were actually antagonistic to, and were active propugnators against the educational standards of the Society. It was probably thought that in the course of generation these men would all die off, and that when the register was composed entirely of men who had been placed there as the result of examination (paid without a fee, I regret to say) a different spirit would prevail. But unfortunately our experience has shown it to be otherwise, and the baneful influence of the trade element is still predominant on the register, to such an extent that it has captivated the judgment of some prominent men in the Society itself, and threatens to overthrow the very principle upon which the Pharmacy Act was obtained.

Pharmacy, as practised by the registered chemists and druggists of this country, is attempting an impossibility; it is seeking to grasp the commercial advantages, which in other callings can be obtained by the exercise of legitimate trade, whilst it desires to retain the rewards which properly belong to professional services. This cannot go on much longer, and pharmacy must make its choice between trade and profession, but before I indicate in which direction I think the choice should be, let me briefly mention one or more of the prominent features which characterizes the two.

The very essence of trade is that it is capable of indefinite expansion, and there is no limit to the extent to which a tradesman may sell his goods at the hands of assistants or through the agency of any number of intermediate persons between himself and the user of the article he sells. Apply this test to pharmacy, and you will see it is impossible for it to expand indefinitely in the fulfillment of its own proper functions, of dispensing the prescriptions which the physician has written for the individual patient, or prescribing for the smaller accidents and ailments to which human beings are liable. There will perhaps spring into your minde instances of the indefinite expansion which has followed the advertising of nostrums, but that is not pharmacy, but in many cases is merely obtaining money under false pretences. You all know Jerome's friend who visited the British Museum to read up the treatment for "hay fever," and plopping conscientiously through the book from A to Z found that the only complaint he had not got was "housemaid's knee," and so it is with nostrums. The complaint is, more often than not, suggested by the literature of the nostrum-monger before the nostrum effects its wonderful cure which is recorded in the testimonial.
The essence of a profession, on the other hand, is that the members of it receive a special education, and give evidence before a legally constituted body that they have been so educated; that the service rendered is personal and direct, and cannot legitimately be multiplied indefinitely through the agency of unqualified persons.

 Tried by these criteria, I think you will agree that pharmacy, in the exercise of its legitimate function towards the public, is a profession and is not a trade. English people through their Legislature admitted this in 1868 when, by statute, they laid down the conditions upon which pharmacy should be carried on, and imposed restrictions of a similar kind to those which had before that belonged to the other professions, and which were not and are not imposed upon any trade. How does it happen that the very essence of pharmacy being a profession, that the Pharmaceutical Society and the Legislature having decided, in effect, that it is a profession, we seem as far off as ever from it being practically recognised as such by the pharmacist and the public? It is due to the excessive preponderance of the trade element and of the commercial spirit amongst the registered men. This has handicapped the Pharmaceutical Society and rendered it impossible for the Society to advance upon the line and in the spirit of the Pharmacy Act. We have seen the kindred profession of medicine increase its curriculum, or period of compulsory training, from three to four years, and again to five years, and in so doing it has steadily and deservedly risen in public esteem and respect, whilst notwithstanding the convictions and earnest desire of the Pharmaceutical Society, we have as yet no curriculum at all, and the voluntary training (for our examination) which our young men undergo, in a vast majority of cases, cannot be described by any less objectionable word than that of cram. The consequence is, that notwithstanding that the English people were willing to accept pharmacy as, and to give it the opportunities of, a profession in 1868, they are almost compelled in 1894, by the conduct of those who practice it, to come to the decision that pharmacy is nothing but a trade after all, and so it comes to pass that the grocer and the company pharmacist are so far on the road to win the rights and the privileges which belong to pharmacy. Pharmacy as a trade is a failure, and I go further and say that pharmacy, as well as medicine, conducted as a trade and in the spirit of a commercial venture ought to fail. If we use our knowledge to exploit human ailments, to excite men's fears and to play upon human credulity for gain, we ought most ignominiously to fail. You will be prepared to hear that my own strong conviction is that pharmacy should realise its privilege and seriously proceed to take steps to accept its responsibilities as a profession, and no time should be lost in setting about it. I will only very briefly indicate the steps which are necessary, and trouble you as little as may be with small details. Our entrance examination should be made a much more stringent test of a young man's intellectual powers and of his school training than it is. It is useless to expect men to be able to grasp the problems of organic chemistry whose knowledge of mathematics has not gone beyond the simple arithmetic which our present examination requires. This examination should include algebra and geometry, the Latin should be extended to a knowledge of the selected authors beyond a mere cram of the meaning of words, history and geography, and a modern language should be included, and the examination should be passed not earlier than at seventeen years of age, but before apprenticeship. Following this should come three years of actual (not nominal) apprenticeship, during which the powers of observation should be cultivated, and by continual exercise in the practical operations of pharmacy, under suitable instruction, all that deftness of manipulation and that wise caution in handling things which is a characteristic of the trained pharmacist, should be acquired. A large amount of knowledge of the physical characters of drugs and preparations would necessarily be obtained during this period, and the apprentice, whose mind was in his work, would certainly do some reading in connection with it. Then should come the curriculum, or the period of enforced study, upon a syllabus taught in recognised colleges and schools throughout the country; this period should not be for less than two years, and the whole time of the student should be engaged in training and preparing for the work of his life. During this two years, at certain intervals the progress of the student should be officially ascertained, and at the end, his fitness to become a pharmacist should be tested by one week or more of examination, written, oral and practical. In the subjects of botany, chemistry and materia medica; and if the result was satisfactory, I would give the qualification and title of pharmacist.

The training and examination should take the student at least as far—I should advocate further in some directions—as our Major examination, and I would abolish all intermediate names which even suggest qualification. When the pharmacist has undergone this, as a minimum of his training and proof of his qualification, I think he will have some right to consider himself, and to be considered by the public, a professional man. But now will arise in your minds the question that having elevated your pharmacist to the status of a professional man, what is he to do, and how is he to live? Medical men, to an enormous extent, dispense the prescriptions for their own patients, and they are exceedingly emphatic in their protest against the pharmacist prescribing.

The treatment and cure of disease are the legitimate functions of medicine and pharmacy in co-operation, and no rigid line of demarcation is possible. Broadly, the operations of surgery, the diagnosis of disease and prescribing belong to medicine, and the preparation and dispensing of the remedies to be used in the treatment of disease belong to pharmacy.

Doctor's dispensing is stated to be one of the chief, if not the chief cause of the ills from which pharmacy is a sufferer, and demands in more or less dignified terms are made that this iniquity shall cease. I make no apology for the existence of this condition of things. Theoretically it is undoubtedly better that dispensing shall be done by the
pharmacist, and prescribing by the medical man, but when we pharmacists claim this as a right and accuse medicine of unjustly usurping our functions, it is well for us to remind ourselves that medical men, although they may not now as frequently as of old take the degree of L.S.A., are the direct and legitimate successors of the old apothecary, and that the dispensing of medicine was their legitimate function. So much was this the case, that there being a doubt as to whether it was invaded by our own Act of 1868, the short Act of 1869 was passed to preserve the right. Then again it is deep rooted in the habits of the English people to expect the doctor to supply the medicine he has prescribed, and any change can only come about by the slow process of educating the patients, and by the exhibition of good will and feeling between medicine and pharmacy. Before it can happen universally, there is no doubt that pharmacy must have acquired such a professional standing and education as will enable it to perform its delicate and confidential function with the tact and reserve which is the outcome of prolonged training. The mistake (a very common one) which pharmacy is making is, that it wants the reward before it has made the effort and suitably equipped itself for the service. I exhort the pharmacists of the future to be unremitting in his efforts to raise himself and his calling to a professional status, and then I predict for him that in the natural course the dispensing of medicines will come to him.

Chemists prescribing is quite as loudly complained of by the doctors, and when I read some of the letters and comments which appear in the medical journals I am almost tempted to fear that for once medicine is thinking more of its share of the pecuniary reward than caring for suffering humanity. There is, however, I am sorry to say, a great deal too much prescribing by chemists, and some of it is of a most reprehensible kind. I know a case where a chemist treated a man suffering from rectal ulcer of the face for two years, all the time buoying the man up with the hope that it was getting better, and that he would cure it, until the face was so bad and the ulcer had spread to such an extent that, when it came under the notice of the surgeon, nothing could be done for the patient. If that chemist had met the man upon the highway and robbed him, he would have been liable to imprisonment; but having got the man into his shop, he not only robbed him of his money, but he rendered it impossible for the man ever again to be restored to health. For the dishonour which such men bring upon pharmacy, and for the irreparable injury which they inflict upon suffering humanity, I should like to give them several years of penal servitude. But there are innumerable small accidents and little ailments to which humanity is liable which quite legitimately come within the province of pharmacy to treat, and the pharmacist, if he is wise, is a much safer man to treat these than the clergyman and the laity, who are ever ready to prescribe for each other upon any and all occasions. The best and wisest exponents of medicine admit this right on the part of pharmacy, and welcome the service which is rendered by it to sufferers. Pharmacy may make some mistakes, but I know it frequently sends patients to medicine long before they or their friends would think seriously enough of the case to do so.

There should be no rivalries or jealousies between medicine and pharmacy, and the better qualified each of these may be to exercise its own share of the duties devolving upon both, the more will each of them respect the rights and the work of the other.

Before I conclude, one word on the principle upon which remuneration should be based. This is a question of the utmost importance to the English public, as well as to pharmacists. John Ruskin says, "You do not pay judges large salaries because the same amount of work could not be purchased for a smaller sum, but that you may give them enough to render them superior to the temptation of selling justice." We cannot err in applying this principle to pharmacy, and deciding that the dispensing chemist must be paid at a rate of remuneration which will enable him to get his living honestly and openly, and render him superior to the temptation to increase his profit and his income by tampering in ever so small a degree with the quality of the drugs he uses, and with the health and may be the lives of dear ones and of men important to the community. His remuneration should also enable him to devote sufficient time and care to every detail of his responsible work, and eliminate a very real source of danger which is unavoidable if the haste and the bustle of trade methods are adopted by pharmacy.

The Conference has entered upon the fourth decade of its existence, and possibly I should have made a better and wiser choice if I had addressed you upon its past achievements and its future prospects, but the other matters upon which I have touched have seemed to me of greater importance. Let me say, however, briefly, that I think the record of this Conference has been eminently an honourable one, and that it has fulfilled in a high degree the functions for which it was called into existence. The story is written in the Year Books, and another phase of it is engraved in the hearts and memories of many of us who have been members almost from the beginning and who have attended a large number of its meetings. It has added to our knowledge, enlarged our experience, and broadened our intellectual grasp of pharmacy, and last, but not least, it has been the means of bringing together, introducing to each other, and cementing friendships between men who practice a common avocation in districts as wide apart as Inverness and Cornwall. In this latter function the excursion on the last day has played no inconsiderable part. Amongst the critics of the Conference there are some persons who affect to sneer at the excursion as if it were mere frivolity, and was at variance with the avowed scientific objects of the Conference. I beg to differ, and to claim for the excursion day a very high place in the work of the Conference. It affords the opportunity, as no other arrangement could do so well, for men to meet; and I am quite sure that my own experience is by no means singular when I tell you that many, very many, of the best friends I have in pharmacy
were first known to me through the opportunity of one of the Conference excursions, and, further, I could not exaggerate to you the benefit which I have received from the numerous conversations and informal discussions which always take place on those days. But it is with societies as with individuals, they tend to decay, and already more than once we have the alarm—the Conference is on its last legs! I do not believe it, as I feel sure it fulfils a purpose in the realm of pharmacy which is too important for the Conference to be left to decay, and that if we neglect the trust which has been handed down to us, our successors will revive it. I would ask every member of the Conference to get at least one other member to join, and I do not think he can use a stronger argument than that, apart from the opportunity of attending and taking part in this annual scientific gathering of pharmacy, the 'Year-Book' which he will receive is worth many times the subscription. The 'Year-Book of Pharmacy' should find a place on the desk of every chemist and druggist in this land. In it he will find abstracts of papers from a larger number of sources than he can possibly consult for himself, and many of these papers may be of great value to him.

There is no occasion to disguise the fact that we do not get as many, or possibly as good, papers sent to the Conference as we should like, but when we consider the needs of a weekly press and the number of small societies, which absorb in the aggregate a large number of papers, our experience need cause us neither surprise nor alarm. I should like, however, to ask many of those who are doing original work, and writing papers in connection with pharmacy, to consider whether there is any place so suitable for them to be read as at these meetings. The authors may feel certain of a larger audience to listen to their papers, and a far more capable set of men to discuss them than can be found at any other time or place. In provincial towns the papers are read to a few local men, and the discussion is taken part in by fewer still, and even at the monthly meetings at Bloomsbury Square the discussions have a great tendency to fall into the hands of very few men. However capable these men may be, they cannot possibly have the wide and varied experience of the aggregate of the men who attend this Conference. I would therefore venture to urge thoughtful pharmacists to contribute papers to this Conference, and I should like them to come in such numbers, that we may be compelled to add another day or two to our meeting.

I mentioned just now the friends whom we have made at these Conference meetings, and before I close I must briefly allude to those we have lost. The first name that will occur to you, I am sure, is that of our genial botanist, the late Professor Bentley, who was President at Nottingham in 1866, and in Dundee in 1867. Many of us knew him first and best at Bloomsbury Square as our dear and honoured teacher, but to many others the Conference must have been the means of their meeting him, and by all was he respected and beloved. He had reached a good ripe age, and of him it might be said—as of many other men who have lived and been true to themselves and their calling—"He has done his work well and earned his rest." The next, an even greater loss to us as a Conference, because of his younger age, and the promise there was in him of greater achievements for pharmacy, is our late Treasurer, Mr. R. H. Davies. I, with many others, made his acquaintance through this Conference, and I feel, as I am sure many of you do, that I have lost a personal friend with whom intimacy would have ripened year by year into stronger bonds.

Gentlemen, in conclusion, during the important business of the next two days I am your chairman and presiding officer, and in exercising the functions of that office, I will endeavour to secure a fair hearing for the many-sided opinions, which in the discussions on the papers are sure to find expression, but I should be afraid of the position if I did not know that the honour of this Conference as a whole is as dear as personal honour to every member of it, and that in those discussions no member will withhold facts which he may be able to contribute to the better understanding of the papers.

Mr. Michael Carteigh, in proposing a vote of thanks to the President for his address, said there was a special fitness in Mr. Martin occupying that position, since he did not think they had had a Newcastle man at the head of affairs since Mr. H. H. Brady, when the Conference was founded. Two out of the three founders were present to-day, Mr. Reynolds and Mr. Schacht, the latter having, he believed, the honour of having first suggested the idea of holding such annual meetings. He had never listened to an address with so much interest as he had that morning. They had had many extremely valuable addresses, some on scientific subjects, others on education, and others on sectional subjects, but at no time within its history had the Conference had pot before it a few plain facts so tersely and plainly. If there was one thing he appreciated it was to see the points of this kind who had an individuality and backbone. The characteristic of this address was manliness from beginning to end. Mr. Martin had spoken plainly, not of their virtues only, but of their faults and failings, and of the difficulties, largely due to ignorance, which beset the path of pharmacy. It was his part to criticise or comment on the address, but he might say that he thoroughly agreed with what had been said as to the relation between medicine and pharmacy. It was a fact patent to all intelligent men, not necessarily pharmacists, that in many cases the man of medicine could not prescribe. He begged to move a hearty vote of thanks to the President for his admirable address.

Mr. G. C. Druc having seconded the motion, Sir Henry Acland said there was one matter he had forgotten to mention before. They often heard that they were in a state of evolution, but that there was a process of evolution backwards as well as forwards; in pharmacy, however, as far as he could judge, after listening to the President's address, the evolution was forward. When they visited the Museum they would see that the University had within the last three or four years established a school reader in materia medica and pharma
cology, whichever it might be called; and he would point out that it would be very difficult to define the limits between those three subjects, and that one of the great difficulties of the future was how far experiments on living animals, and so on, should form part of the necessary studies of students.
Whether in pharmacy and materia medica, or whether only in medicinal knowledge would go, but one person could not hold it all. Still, the University had very properly instituted a special course of materia medica, and he was sure they would all be glad to hear that Dr. Lauder Brunton had been appointed Examiner.

The motion was put by Mr. Cartelagh and carried unanimously.

The President, in acknowledging the vote of thanks, said he was aware that of late years the medical curriculum included a clinical study of drugs; but there was a time when the knowledge of drugs was to the medical student a minus quantity. It seemed to him of vital importance that whatever else a man ought to know something about the treatment and cure of the patient he visited.

RECEPTION OF DELEGATES.

Mr. W. A. H. Naylor (Hon. Sec.) then read the following list of delegates:

Pharmaceutical Society of Great Britain.—Messrs. M. Cartelagh (President), W. G. Cross (Vice-President), R. Hampson (Treasurer), Messers. Atkins, Bottle, Gotlieb, Grose, Hills, Martin, Martinale, Schacht-Southall, and Young; the Editor, Sub-Editor, and Secretary.

North British Branch.—Messrs. J. Laidlaw Ewing (President), C. Kerr (Vice-President), Currie, Davidson, Gibson, Lunan, and Mabon.

Pharmaceutical Society of Ireland.—Messrs. G. D. Beggs (Vice-President), Coneyham, and Walls, jun.

Aberdeen and North of Scotland Society of Chemists and Druggists.—Messrs. Johnston, Kay, and Paterson.

Brighton Association of Pharmacy.—Messrs. W. H. Gibson (President) and W. W. Sams.

Leeds Chemists' Association.—Messrs. R. Reynolds (President) and G. Ward.

Liverpool Chemists' Association.—Messrs. Conroy, Smith, Symes, and A. S. Buck.

London Chemists' Assistants' Association.—Messrs. Gane, Harrison, Jones, Parry, and Strother.

Sunderland Chemists' Association.—Messrs. Harrison and Ranken.

Manchester Pharmaceutical Association.—Messrs. Cooper, Kemp, and Johnstone.

Nottingham and Notts Chemists' Association.—Mr. C. Bolton.

Edinburgh and West of Scotland Pharmaceutical Association.—Messrs. W. L. Currie (President) and A. Kinninmont.

Midland Pharmaceutical Association.—Messrs. R. D. Gibbes (President), F. G. Gibson (Vice-President), Prosser, Aloxco, Perry, A. Southall, C. Thompson, H. Hutton, W. Jones, J. Barclay, J. Liverasshe, and C. F. Jarvis.

Bournemouth Chemists' Association.—Messrs. Bridge (President), Hardwick, Trove, Spinney, and Bilson.

Cambridge Chemists' Association.—Mr. R. S. Campkin.

Letters of apology for their absence had been received from Messrs. F. B. Benger, E. C. Stanford, Peter Bos, Ebert (Chicago) N. M. Grose, E. F. Harrison, Walter Hills, J. C. C. Payne, L. Siebold, and Peter McEwan.

REPORT OF THE EXECUTIVE COMMITTEE.

Mr. Naylor (Hon. Sec.) then read the following report of the Executive Committee:

REPORT OF THE EXECUTIVE COMMITTEE.

In presenting the thirty-first annual report your Committee is glad to be able to state that general interest in the work of the Conference shows no sign of diminution. Increased membership is still, how-
**Financial Statement for the Year Ending June 30, 1894.**

The Hon. Treasurer in Account with the British Pharmaceutical Conference.

The Treasurer (Mr. John Moses) being called upon to read the financial statement, said he must first say a word in reference to his predecessor, the late Mr. R. H. Davies. His thoroughly and with everything which had been said by the President, and in the report of the Executive. Knowing Mr. Davies personally for a great many years, he knew how true those words were. He was a most painstaking man, a man of great accuracy and minuteness, and in every way a man of science; one who knew thoroughly every subject on which he professed to speak. With regard to the financial statement, it shewed to some extent the depression which had been such a marked feature lately in all parts of the world, but not so much as might have been feared. For a voluntary body representing the professional, scientific, and social side of pharmacy to pursue its course so evenly was evidence of a strong desire on the part of pharmacists as a body for something which merely commercial questions could not satisfy. Still, the number of members was not satisfactory, and many thought that if they had better means of making known the advantages which the Conference could confer on individual pharmacists, the number would represent not 10 per cent., but more like 50 per cent. of the pharmacists in the United Kingdom. If ever that could be accomplished they would be able to do a great deal more good, and many publications which now had to be charged for might be given to the members free. The great thing to aim at was for each member to act as an apostle, and bring in new disciples.

The President having certified that the accounts had been duly audited, moved the adoption of the report and financial statement. Mr. Umney seconded the motion, which was carried unanimously.

**The Unofficial Formulary Committee.**

Mr. Martindale next read the report of the Unofficial Formulary Committee, as follows:

To the British Pharmaceutical Conference in session.

Since our last meeting the Committee have, with the sanction of the Executive, produced a new issue of the "Unofficial Formulary," which is now ready for sale. They have added four new formulae, viz.:

1. Colloidiun Stypitica, Extractum Belladonnae febri Alcoholicum, Liqueur Bromo-Chloralis Compositus, and Syrupus Acidis Hydriodicis. Several alterations and corrections have been made, which further experience of the preparations have rendered necessary. These consist principally in lessening the acidity of some of the syrups, thereby rendering them more stable and palatable, and in an improved formula for Colloidiun Belladonnae. The latter presented difficulties in the way of preparing it from a liquid extract sufficiently
concentrated to be stable. They have overcome these by using a solid alcoholic extract of belladonna leaf, which must be assayed at the time of preparing the collodion, so as to obtain an uniform product.

Wm. Martindale, 
Chairman of the Formulary Committee.

(To be continued.)

Parliamentary and Law Proceedings.

POISONING CASES AND INQUESTS.

ACCIDENTAL POISONING BY LINIMENT.

An inquest was held on July 25 by Mr. S. Smelt, deputy city coroner, on the body of Hannah Mathier, aged 73 years, who lately lived in Queen's Road, Manchester. The deceased had suffered from bronchitis, and on Monday night drank by mistake for medicine a spoonful of a liniment which she was using for outward application. Death resulted on Tuesday. A verdict of accidental death was returned. The coroner remarked that there ought to be legislation concerning the use of medicines, and also to have a distinctive shape of bottle for poisons. In Germany a bottle was used for poisons of a shape that could not be mistaken, and in some hospitals in this country fluted bottles coloured blue were used, so that people could tell them in the dark. If there had been a law compelling the use of distinctive bottles for poisons this accident would not have happened.—Manchester Guardian.

POISONING BY CARBOLIC ACID.

Mr. T. J. Sworiter, coroner, held an inquest at The Oak, Stanstead Abbotts, on Tuesday, July 17, upon the body of George Frederick Winterm, aged 3 years and 3 months, the son of a tailor of that place, who died on Saturday last through drinking a dose of carbolic acid by mistake.—Hertford Chronicle.

POISONING BY CHLOROFORM.

Mr. A. Braxton Hicks held an inquiry, on July 24, into the death of Septimus Collins Burton, aged 35 years, a chemist's assistant, late in the employ of Mr. Farmer, a chemist, of 106, High Street, Putney, who was found dead in bed on the morning of July 21. It was proved that the deceased, who was married, and has left three children, suffered from sleeplessness and neuralgia. To obtain sleep he was in the habit of taking large quantities of chloroform, sometimes as much as half a pound a day. Medical evidence showed that death was due to chloroform, but how the poison was obtained was unexplained. It was suggested that it had been purchased from a wholesale house. The jury returned a verdict of "Death from misadventure," and added a rider that the attention of the Privy Council should be drawn to the large quantities of chloroform sold by wholesale or retail chemists. The coroner remarked that two pound bottles of chloroform had been found in the deceased's room. He would have the matter fully inquired into.—Morning.

POISONING BY POTASSIUM CYANIDE.

On Saturday, July 14, Mr. W. Wynn Evans, the East Denbighshire coroner, held an inquest at the Fairfield Tavern, Wrexham, on the body of a tailor, named John Henry Williams, aged 37. The deceased's landlord said he came home on Friday morning, and said he had to go to work in the afternoon. He had been drinking since the previous Saturday, and had brought something home to steady his nerves. He went to bed, and when he went to call him at dinner time she found he was dead.—Dr. Parry Jones said the symptoms were consistent with poisoning by cyanide of potassium. —Mr. C. O. Cadcott, manager to Mr. J. F. Edisbury, chemist, High Street, Wrexham, said the deceased came into the shop, and said he wanted some cyanide of potassium to clean some gold lace. As witness knew deceased and also knew that tailors used the poison in their business, he supplied him with half an ounce.—W. Wynn, a fellow workman of the deceased, said deceased told him some time ago that cyanide of potassium, in very small doses, was a grand thing to take after anyone had been on the spree. The coroner said there was a doubt as to whether it was the intention of the deceased to take his life, and he thought that taking the evidence into consideration, the jury would be justified in bringing in a verdict of "Death from misadventure."—This was accordingly done.—Chester Advertiser.

POISONING BY ATROPINE.

On July 16, an inquest on the body of Mr. Pelham Parker, who died under peculiar circumstances, was held at the Prince of Wales Inn, Blacktop, by Mr. Gray. He was deceased's medical attendant. He was called to Mr. Parker at 1.45 p.m. the previous day, when he found him suffering from atropine poisoning, and unconscious. Atropine was the active principle of belladonna. A small bottle (produced), labelled "Atropine Eye Drops," was given to witness as the one taken from deceased. Witness had sent similar bottles containing laudanum to deceased for his son's carache.—Margaret Parker, the widow, said that her husband was in the habit of having warm baths on Sunday mornings. He had one on the previous day, and then returned to bed. About eleven o'clock she entered his bedroom and saw him standing with a small bottle in his hand. He said it was laudanum, and he was taking it to make him sleep. Witness took it from him, and two hours afterwards the deceased became very ill. She gave him an emetic of mustard and water, which he took willingly, and after he had been sick she thought all was well. He came downstairs and read the paper, and appeared to be all right up to about two o'clock, when he became unconscious, in which state he remained until 2.30 on Monday morning, when he died. The jury retired to consider their verdict, and upon their return Mr. Whittle, the foreman, said the jury came to the conclusion that Mr. Pelham Parker had met his "Death by misadventure."—Lancashire Evening Express.

THE CHEMISTRY OF IPECAUCANHA.

BY DR. R. H. PAUL AND A. J. COWNLEY.

In a previous paper on this subject* we showed that, contrary to the generally received opinion, the substance hitherto known as emetine is a mixture of two or more alkaloids, and that in order to determine the value of different kinds of ipecacuanha from the amount of alkaloid contained in them, further knowledge of these substances was requisite. Our inquiry is now sufficiently advanced to admit of the results being published. But before entering upon a further statement of the results we have obtained in our investigation of ipecacuanha, it is desirable to summarize the accounts given by previous inquirers, because of the manifold discrepancies they present in regard to the character of the substances obtained, and also because of the uncertainty prevailing as to the mode of the drug operated upon.

The investigation of ipecacuanha from a chemical point of view was first undertaken by Pelletier shortly after Sertürner's discovery of morphins. He showed that the medicinal properties of the drug were due to a "proximate principle" or "materie vomitive," to which he gave the name of emetine, from ἐμεθή—to vomit, and a formula for its preparation was introduced into the French Codex in 1818.† The product so obtained—amounting to about 16 per cent. of the drug—was little more than a concentrated alcoholic extract. It had the form of transparent scales of reddish-brown colour, acid reaction and bitter taste, very deliquescent, soluble in all proportions in water or alcohol, but insoluble in ether. The aqueous solution gave a green colour with ferric salts and copious flocculent precipitates on addition of basic lead acetate or infusion of nut galls. It was, in fact, a pharmaceutical preparation rather than a distinct chemical substance, and was essentially a saline compound of the basic constituents of ipecacuanha, with an acid somewhat analogous to jenmic acid.

Subsequently, Pelletier succeeded, in conjunction with Magendie, in obtaining a purer product of distinctly basic character, which was submitted to analysis by Dumas.§ and found to have an elementary composition, which was represented as corresponding with the formula $C_{26}H_{23}N_5O_5$.

This base was described as white pulverulent substance, sometimes slightly yellowish, and becoming colored on exposure, but not deliquescent; soluble in 50° C., very slightly soluble in water, freely soluble in alcohol, and insoluble in chloroform. It had a marked alkaline reaction and neutralized acids, but did not form precipitates with acid solutions sometimes showed signs of crystallization. An aqueous solution did not give a precipitate on the addition of basic lead acetate. It was, therefore, very different from the emetine of the French Codex, and legend found it to be three times as effective medicinally.

‡ Codex Med., 1818, p. 179.

- Various methods of preparing emetine were subsequently suggested by Callou, Merck, Reich, and Leprat; but probably none of them furnished a perfectly pure and chemically individual substance.

The examination of the alkaloid obtained from the official Brazilian ipecacuanha by Reich* is chiefly noticeable for the results of the elementary analysis leading to the formula $C_{26}H_{23}N_5O_5$.

100. 100.

The ipecacuanha then employed for medicinal purposes in France was probably the officially recognized drug imported from Brazil under the name of Rio ipecacuanha, the produce of a plant belonging to the genus Cephaelis, and growing in the province of Mato Grosso, situated in the basin of the River Paraguay.† The Codex of 1758 enumerated three kinds of the official drug—ipecacuanha fusa, ipecacuanha cimerca, and ipecacuanha candidor,—which would probably correspond with the three varieties—brown, grey, and white—mentioned by Pelletier in his memoir as being the kinds most used.§ The botanical source of these varieties is uncertain, for Pelletier's statement that the brown ipecacuanha examined by him was the produce of Psychotria emetica was subsequently corrected by Guibourt.|| Besides the varieties attributed to the genus Cephaelis, two other kinds of ipecacuanha appear to have been official at that time, the "strated" and "undulated."||* Other kinds of ipecacuanha were imported from Pará and Bahia under names taken from the provinces of Brazil, where they were collected. Some of them were possibly derived from plants of the genus Cephaelis, and others from species of Ionidium, etc.

The gradually increasing scarcity and high price of the Brazilian drug, as well as the success attending the importation of cinchona bark from New Granada, subsequently led to the introduction of a drug from that part of South America under the name of Carthagenes ipecacuanha, obtained from a plant growing in great abundance on the banks of the Magdalena river, and considered by Guibourt‡‡ to be a different and botanically undetermined species of Cephaelis. In 1869

§ Codex Med., 1758, p. 63.

||††"Histoire naturello des drognes simples," iii., 29, 1859.

1259.
Lefort directed attention to this drug,* pointing out that, although differing in appearance from Brazilian ipecacuanha, it might be equally useful medicinally, and could, in that case, be recognised officially as a valuable supplement to the Brazilian drug. But before its use in pharmacy could be adopted, better knowledge of its components and of its actual relation to the official drug as a therapeutical agent was requisite.

In order to solve that problem, and, with the view of definitely settling the question whether the ipecacuanha of New Granada could be substituted for the official drug, Lefort made a comparative examination of the two kinds, by determining the amount of alkaloid contained in them respectively.†

Following in the track of the observations made by Pelletier and Dumas, that the alkaloid of ipecacuanha formed with tannin a compound characterised by its very sparing solubility in water, Lefort had recourse to that method for ascertaining the amount of alkaloid in the ipecacuanha of New Granada as compared with that of Brazil. The dry powdered drug was exhausted with strong and weak alcohol successively, the alcoholic liquor evaporated to a syrupy consistence, and the residue mixed with from five to twenty volumes of water. To the filtered liquor a concentrated solution of tannin was added in slight excess, and the precipitate thus formed was well washed, dried, and weighed.

Operating in this way the conclusion was arrived at that the ipecacuanha of New Granada contained rather less alkaloid than that of Brazil, the relative amounts of tannate obtained being 1:341 and 1:449 per cent.

Another method adopted for comparing the two kinds of ipecacuanha as to their contents of alkaloid was based upon the sparing solubility of the nitrate in water. The results so obtained were much the same as in the previous case so far as the amount of alkaloid was concerned; but the identity of the basic constituents in the two different kinds of ipecacuanha appears to have been not exactly assumed by Lefort.

In a subsequent memoir, published during the same year, Lefort gave the results of a more particular study of the properties and composition of the alkaloid obtained from ipecacuanha.‡ The method adopted for its extraction consisted in treating the syrupy residue of an alcoholic extract with caustic potash and chloroform. After evaporating the chloroform solution, a product was obtained consisting chiefly of the base mixed with a very dilute acid, and by adding just enough ammonia to the clear solution, the base was precipitated almost free from the resinous substance, the last portions of which were removed by digesting the precipitate with ether, after washing with water and drying.

The base thus obtained was a very light powder, of a white or grey colour, according to the degree of purity, almost inodorous and of bitter taste. It melted at 70° C., and on exposure acquired a brownish colour, but did not deliquesce. It was very sparingly soluble in cold water (1 in 1000), readily soluble in alcohol and chloroform, but very slightly soluble in ether, and it was uncrystallizable. The base was readily dissolved by caustic potash or soda, and the solutions rapidly absorbed oxygen from the atmosphere. It was less freely soluble in ammonia, and when mixed with lime or magnesia, it became yellow on exposure. It was readily dissolved by most acids, neutralising them and forming soluble uncrystallizable salts; with nitric acid it formed a very slightly soluble salt, which was considered to be the most distinctive characteristic of the base. Potassium iodide and alcoholic solution of iodine gave precipitates very sparingly soluble in water. Mercuric chloride and potassium hydrargyrodioic gave white precipitates, insoluble in water and soluble in alcohol. The platinocloride was soluble in water, but only sparingly soluble in alcohol. Ammonium molybdate gave a precipitate as well as basic lead acetate.

The base obtained by Lefort was not analysed, but with the aid of the analytical data obtained by Pelletier and Dumas he endeavoured to ascertain its molecular weight from the saturating capacity, and the composition of its salts, by determining the amounts of sulphuric acid and chloroform in the neutral sulphate and hydriodic acid. On that basis, and assuming the alkaloid to be identical with the substance analysed by Dumas, it was inferred that its formula was $C_{n}H_{2n}N_{2}O_{4}$.

The subject was next taken up by Professor Gignard,§ who applied the method of treatment with lime and ether for the extraction of the basic constituent of ipecacuanha, obtaining it in a clearer, colourless, and in relatively large quantity, a result that was not consistent with the description of emetine the accepted.

A dry alcoholic extract of the drug was warmed with an equal quantity of water, mixed with and a half times its weight of lime, and the precipitated mixture percolated with hot ether, in the proportion of one litre to 100 grammes of extract. By that treatment it was assumed that the whole of the alkaloid might be extracted. The solution was then shaken with sufficient hydrochloric acid to form a salt, and after separating the ether, the base—precipitated from the aqueous solution by ammonia, washed, and dried—presented all the characters attributed to emetine. By careful evaporation of the aqueous solution of hydrochloride, the salt was obtained in a crystalline condition. This result, contrary to the previous experience of Lefort and others that all salts of emetine were uncrystallisable, enabled Gignard, by repeated recrystallisation, to prepare

* Carthageana ipecacuanha was imported into France in boxes or cases by way of Havre, while the Brazilian drug was imported in barrels or by way of Bordeaux.

By these results Gienard was led to the conclusion that the substance analysed by Dumais, as well as that subsequently obtained by Lefort, could not have been sufficiently purified.

As a consequence of the question raised by Gienard as to the purity and individuality of the substance obtained by previous experimenters, a further paper was published by Lefort and Wurtz, in which they suggested an improved method of preparing emetine by mixing an aqueous solution of the alcoholic extract of ipecacuanha with a saturated solution of potassium nitrate. The washed precipitate of nitrate, requiring 100 parts of water for solution, was dissolved in hot alcohol, mixed with lime and, after evaporating off the alcohol, the dry residue was extracted with ether. The base was then submitted to further purification until almost colourless, and was assumed to be absolutely pure. Analysis gave results corresponding with the formula C_{16}H_{22}NO_{17}.

As further confirmation of the formula based on these results, an analysis of the nitrate showed that its composition would be represented by the formula C_{16}H_{22}N_{2}O_{18}+2NO.H.

Whatever may have been the chemical character of the substances subjected to analysis for the purposes of the investigations already referred to, there cannot be much doubt that the substances met with in trade under the name of emetine were impure and sometimes contaminated with a considerable amount of resin or of the constituent of ipecacuanha which resembles tannin. That circumstance was pointed out by Podwysotzki, who proposed the use of ferric chloride to get rid of this impurity. The product he obtained was snow white, it melted at 65° to 66° C., had a strong alkaline reaction, was readily soluble in ether, and very sparingly soluble in water. By the slow evaporation of an ether solution of the base partial crystallisation took place but none of the salts were obtained in a crystalline state. The base was sparingly soluble in cold petroleum spirit or benzene, but easily soluble when heated, separating again on cooling in white fumes.

Some years afterwards the alkaloid of ipecacuanha was again submitted to investigation by Kunz, who adopted a modified form of the method suggested by Podwysotzki for its preparation. The product he obtained was amorphous and perfectly colourless, but rapidly became yellow on exposure. It was by no means insoluble in caustic alkalies, very sparingly soluble in cold water, cold petroleum spirit, or ether, but more freely by heating. By the rapid evaporation of a concentrated ether solution, distinct acicular crystals were sometimes obtained. When perfectly free from moisture or adherent petroleum ether, the melting point was from 68° to 74° C. The retention of minute traces of solvent was also considered to have been the cause of the differences between the analytical results of previous observers, and when that was provided against, analysis gave results leading to the formula C_{16}H_{22}N_{2}O_{6}.

In none of the memoirs above referred to is there any statement as to the kind of ipecacuanha operated upon, and it was probable that some of the discrepancies they present might be ascribed to differences in the drug examined. The general probability that ipecacuanha might contain more than one alkaloid was recognised by Gienard as well as by Lefort and Wurtz, but in neither case was any definite conclusion arrived at on this point, and the alkaloid obtainable from ipecacuanha has hitherto always been regarded as a substance having distinct chemical individuality.

We have already shown that this is not the case, and further inquiry has shown that in the ipecacuanha of Brazil, as well as that of New Granada, there are at least two distinct bases presenting well-marked differences in their physical characters and salts.

One of them is soluble in caustic alkali, and can be obtained in a crystalline state from an ether solution. The other is insoluble in caustic alkali, and it appears to be uncrystallisable. There is a further distinction between the salts of these two bases: those of the first-mentioned being uncrystallisable, while the halogen salts and the nitrate of the other base can be crystallised.

For reasons stated below we propose to retain the name of emetine for the base insoluble in caustic alkali, and to apply to the other base, which has now been isolated, the name of cephaline.

Both these bases are present in Brazilian ipecacuanha and also in Carthagena ipecacuanha. In the latter drug cephaline appears generally to preponderate over emetine, and probably that is also the case in the stalky portion of the Brazilian drug. But if emetine be the active constituent of ipecacuanha, it would seem probable that the New Granada drug has a medicinal value little, if at all, inferior to that of the Brazilian drug now met with in commerce.

In the examination of Brazilian ipecacuanha the following method was adopted. A quantity of the drug was extracted with
alcohol, the liquor mixed with basic lead acetate until no further precipitate was formed, the filtered liquor evaporated to dryness, and the residue dissolved with weak acid. The clear solution was mixed with ether, ammonia added in slight excess, and shaken. The ether solution of alkaloid was then shaken out with weak sulphuric acid, and the base precipitated from the aqueous solution by soda in excess. The precipitate after washing and drying amounted to 1.34 per cent. It still retained some base soluble in caustic soda, for the separation of which repeated treatment was necessary.

The product thus obtained was therefore dissolved in acid and shaken with caustic soda in presence of ether, this operation being repeated until the base soluble in caustic alkali had been completely separated. The insoluble base was then converted into hydrochloride, the salt re-crystallised from water,* and the base finally precipitated by ammonia.

The alkaline solution acidulated and then shaken with ether and ammonia gave the base soluble in caustic alkali, amounting to 0.6 per cent.

In the examination of New Granada ipecacuanha the powdered drug was mixed with lime and extracted with amyl alcohol, the subsequent separation of the base being effected as in the previous instance.

EMETINE.—This base is apparently amorphous, and almost colourless; it melts about 68° C., is strongly alkaline to litmus, and neutralises acids completely. On exposure to light it acquires a yellowish colour. It is readily soluble in alcohol, ether, chloroform, or benzene; but only sparingly soluble in hot petroleum spirit or in water.

On evaporating any of these solutions the base is left in the form of a transparent varnish.

The sulphate, acetate, and oxalate are very soluble in water or alcohol, and apparently uncrystallisable; the hydrochloride, however, may be obtained in a crystalline condition by evaporating a water solution slowly, or by adding ether to an alcoholic solution. It crystallises from a water solution in radiating groups of silky filaments.

A five per cent. solution of the hydrochloride mixed with potassium bromide or iodide gives dense precipitates, which dissolve on addition of alcohol, and by slow evaporation both the hydrobromide and hydriodide of the base crystallise in tufts of silky needles.

The nitrate is very sparingly soluble in water, and separates as a resinos mass on adding potassium nitrate to a five per cent. solution of the hydrochloride. It is more freely soluble in alcohol, and by gradually adding ether to the solution is deposited in crystalline tufts.

The platinocloride is a pale buff coloured amorphous precipitate, almost insoluble in water or alcohol.

Analysis of the base gave the following results, corresponding very closely with those obtained by Génard, and with the formula \(\text{C}_\text{H}_\text{N}_\text{NO}_\text{=248} \):

By titrating the base it was found to require for complete neutralisation 14.56 per cent. HCl.

Base.  
HCl.  
0.23 required 4.3 C. x \(\text{0.078} = \text{0.335} = 14.56\) per cent.  
This corresponds to 12.71 per cent. HCl in the salt, the calculated quantity being 12.83 per cent.

The hydrochloride dried until constant at 100° C. did not show any further loss at 120° C.

\(\text{AgCl. HCl.} \)

0.163 gave \(\text{0.828} = \text{0.2105} = 12.91\) per cent.

Calculated for \(\text{C}_\text{H}_\text{N}_\text{NO}_\text{HCl}=12.83\).  
The platinocloride dried until constant at 100° C. was partially decomposed at 120° C.

Pl.  
208 gave \(\text{0.451} = 21.63\) per cent.

Calculated for \(\text{C}_\text{H}_\text{N}_\text{NO}_\text{PtCl}_\text{2HCl} = 21.52\) Pt.

Molecular weight 506

CEPHALEINE.—This base, when precipitated from a solution of one of its salts by ammonia, is colourless, but, like emetine, it acquires a yellow colour on exposure to light: it is very much less soluble in ether than emetine and is very sparingly soluble in cold petroleum spirit, but with the aid of heat it is more freely dissolved, and, on cooling the solution, is again deposited in a flocculent form. By evaporating a solution in alcohol, ether, or petroleum spirit, the base is left in the form of a faintly yellowish transparent varnish; but in a closed vessel a concentrated ether solution deposits after some time bunches of delicate silky crystals, which appear to be formed more readily in the presence of water. The ammonia precipitate melts at about 102° C. The crystals from ether melt in a capillary tube at 96° to 98° C. By exposure on a watch glass to a temperature of 100° there is a loss of weight amounting to 4.78 per cent.; at 120° C. there is no further loss, but the substance then acquires a brown colour without melting, and apparently undergoes some alteration which has not yet been studied.

The salts of cephaeline are apparently uncrystallisable, but otherwise much resemble the corresponding salts of emetine. The platinocloride is yellow and decidedly darker in colour than the corresponding salt of emetine.

Analysis of the anhydrous base gave the following results corresponding with the formula \(\text{C}_\text{H}_\text{N}_\text{NO}_\text{=248} \):

By titrating the base, it was found in two experiments to require for neutralisation 15.66 and 15.67 per cent. HCl, the calculated quantity for the formula given above being 15.598 per cent. The mean of these results would give 15.54 for the percentage amount of HCl in the salt, as against 15.46 calculated.

The platinocloride gave 22.38 per cent. platinum, the calculated quantity being 22.21 per cent.

The physiological action of these two bases is
now being investigated, and for the present we are unable to do more than state that both emetine and cephaline act as emetic in doses of about one-sixth of a grain, causing at the same time a feeling of considerable depression.

It may be inferred from the foregoing description of the characters of these two bases and of their salts, that the only instance in which a base of definite chemical individuality has hitherto been obtained from ipecacuanha was the investigation of the drug by Glénard. The accounts given by other chemists of the products obtained by them are evidence that they either consisted mainly of cephaline, or were indefinite mixtures of that base with emetine. Their statements that the base which they took to be emetine was soluble in caustic soda and in hot petroleum spirit, but only sparingly soluble in ether, show that it contained but little, if any, of the base isolated by Glénard. The methods of preparation adopted by Podwysotski and Kunz also suggest the probability that the product they obtained was chiefly cephaline. As a consequence, the analytical data given by these chemists are of little value.

Glénard's results, however, are of a different nature. The methods of preparation and purification adopted by him, viz., extraction by means of lime and ether, and re-crystallisation of the hydrochloride, are precisely the conditions most favourable for eliminating cephaline and ensuring the production of pure emetine. There was therefore every probability that, by this fortunate coincidence, a definite product would be obtained. Moreover, in regard to the characters and composition of emetine, Glénard's results are so completely in accord with those we have obtained, that there is no doubt as to the identity of the substance described by him under that name.

In conclusion it may be stated that, consistently with the facts above stated, examination of the substance met with in trade under the name of emetine, has shown that it is a mixture of the two alkaloids above described.

PATENT FOR A MEDICINAL PREPARATION.

"A NEW OR IMPROVED LOTION FOR THE CURE OF RINGWORM."

"I, Thomas John Mott, Dairy Farm, Littlesport, Cambridgeshire, farmer, do hereby declare the nature of this invention, and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:"

"My invention relates to a new or improved lotion for the cure of ringworm, and has for its object to provide a lotion which will quickly and effectually cure that disease.

"In carrying my invention into practice I take of the following ingredients in or about the proportions stated below:—White copperas, 1 oz., Acetate of lead, 1 oz., Salammoniac, 1 oz., which are added to one pint of water, and when dissolved is ready for use.

"The lotion is applied by means of a sponge about every six hours in ordinary cases, but could of course be applied more or less frequently, according to the acuteness of the disease.

"Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—The new or improved lotion, consisting of white copperas, acetate of lead, salammoniac, and water, in or about the proportions herein stated, and for the purpose specified."
LORD SALISBURY ON SCIENTIFIC IGNORANCE.

In officiating as President of the British Association at the meeting in Oxford, the Marquis of Salisbury has had to perform a task of more than ordinary difficulty. Being Chancellor of the University as well as President of the Association he had to tender as well as accept the welcome accorded by one body to the other. As President representing British science, and as Chancellor, those eager to learn from its high priests, the position was rendered still more embarrassing by the necessity of having, as a layman, to deliver an address to the most competent scientific audience in the world.

Lord Salisbury was, however, fully equal to the emergency. His address did not present a review of the past year’s scientific progress; but it was unprecedented for the novelty of its subject matter, for it surveyed the less interesting and more important area of ignorance. Directing attention to that vast region of impenetrable mystery, in relation to which the knowledge we possess is but a small oasis in the desert, his Lordship selected for his theme three or four of the most important physical problems which it has been the effort of the last century to solve.

First among these scientific enigmas was the nature and origin of the chemical elements. Referring in the first instance to the almost irresistible conviction that the existence of these bodies is a strange anomaly concealing some much simpler state of facts, it was shown that hitherto all attempts to trace a common origin have failed as signalling as the transmutation attempted by the alchemists of the Middle Ages. The subsequently renewed hope that the atomic doctrine of Dalton might lead to a solution has, when subjected to the tests of the laboratory, always received the clear and certain reply that facts do not offer the slightest foundation for the theory advanced on that basis. The discovery of spectrum analysis, by means of which such marvellous additions have been made to our knowledge, has added new difficulties and left us as ignorant as ever as to the nature of the capricious differences by which elementary atoms are distinguished, and as to the causes to which those differences are due.

The brilliant revelation of the periodic law by Mendeleeff, and its subsequent remarkable confirmation, dimly point to some identical origin of the co-ordinate families of elements. But that discovery has rather thickened than dissipated the mystery. The application of the comforting word “evolution” is inadmissible for alleviating our perplexity and masking the gap in our knowledge, since the elements do not breed, and consequently their ordered differences cannot be ascribed to accidental variations, perpetuated by heredity under the influence of natural selection. Greatly as Dalton’s, Kirchhoff’s and Mendeleeff’s successive triumphs of research have added to our store of knowledge, they have done but little towards solving the problem which the elementary atoms present. The dream which lured the alchemists to their tedious labours has neither been realised nor refuted, and the boundary of our knowledge in this direction remains where it was centuries ago.

The next instance given of a riddle which has hitherto defied the scrutiny of science is the entity called the “ether.” Since the time of Torricelli and Fresnel the conception of this entity has received notable extension through the researches of Maxwell and Herz, showing that the undulations by which electricity travels through space probably take place in the same medium. But though the mystery of the ether has thus been made more fascinating, it remains as inscrutable as ever. Even its solitary function of undulating is performed in a fashion so abnormal as to cause infinite perplexity. Instead of transmitting impulses by waves travelling backwards and forwards in the path of their advance, the ether undulates athwart the path of the wave’s advance. Lord Kelvin’s recent discovery of a condition under which a fluid may be conceived to undulate in this eccentric manner without outraging the laws of mathematics was merely mentioned by Lord Salisbury as a subject on which he could not judge whether it is to be regarded as furnishing a permanent solution of the difficulty or merely what diplomatists call a modus vivendi. In any case it leaves our knowledge of the ether in a very rudimentary condition, while in regard to the counteracting and complementary forces of positive and negative electricity, the theory of electrical ether waves leaves our knowledge of their cause as slender as that possessed by Franklin a century and a half ago.

But among the instances where obscurity hangs over problems which the highest scientific intellects have been investigating for generations there is none so striking as animal and vegetable life. The artificial production of compounds which are naturally found only in vital organisms has been considered to afford sufficient reason for demurring to the use of the term “vital force” to define the mysterious impulse which strikes across the ordinary laws of matter and twists them for a moment from their path. But Lord Salisbury remarked that the counterfeit production of their compounds does not enable us to bring an organism into existence and cause it to run its natural course of change, and he pointed to the cause by which those results are effected, as the unknown force which continues to defy not only our imitation, but our scrutiny.

The concluding portion of the address was devoted to reviewing the deficiency of our knowledge in regard to the cause and origin of life.
the problem arose many millions of years ago. In treating of the Darwinian doctrine of the origin of species and the remarkable influence which it has exercised, the conflicting views of biologists and mathematicians, in regard to the difficulties arising from it, were criticised with a keenness approaching the satirical. This was especially the case in the reference to Weismann’s argument, that the principle of natural selection must be accepted because “it is inconceivable that there should be another principle capable of explaining the adaptation of organisms without assuming the help of a principle of design.” This use of the argument of design as a "reductio ad absurdum" Lord Salisbury regards as an illustration of the revenge so surely brought by the whirligig of time. He objects to such an argument as that used by Weismann, as being out of place in science, although it may sometimes be admissible in politics, and holds that if facts will not provide a sound theory, confession of ignorance must be our only reasonable answer to the riddles which nature propounds.

THE BRITISH PHARMACOPOÉIA.

We are informed by the Secretary of the General Medical Council that, in connection with the subject of the Imperial extension of the Pharmacopée, and the proposal of the Medical Council to extend the usefulness of the work to the colonies and India, replies have been received by the Council, through the Colonial Office, from the Bahamas, Barbados, Bermuda, British Honduras, the Cape of Good Hope, Cyprus, Jamaica, Malta, Queensland, St. Helena, Sierra Leone, South Australia, Tasmania, Western Australia, and Zululand. Replies from other colonies are expected. A representative from Canada has visited London and has had interviews with members of the Council on the subject.

In all cases the proposal of the Council has been accepted. In some of the colonies neither climatic nor other conditions point to any special adaptations of the Pharmacopée, but offers are made to collect and forward any desirable information. In others medical and pharmaceutical committees have been appointed to consider and report on the matter. In some colonies the prevailing high temperature leads to requests for ointments of a commensurate melting-point, for extracts having the minimum of moisture, and for pill masses less liable to become hard. The omission of costly drugs that are without special advantages and can easily be substituted is recommended in some of the communications. Several suggestions concerning individual preparations are made. Most of the valuable indigenous materia medica seem, as might perhaps be expected, to have already found their way into the British Pharmacopée.

THE CONJOINT EXAMINING BOARD.

The Secretary of the Conjoint Examining Board in England of the Royal Colleges of Physicians and Surgeons states that the following new regulations will come into force on and after the lst October next, namely: — “A candidate referred in chemistry and physics will be required before being admitted to re-examination to produce a certificate that he has received further instruction in those subjects to the satisfaction of his teachers, at an Institution recognised for the purpose by the Examining Board, for a period of not less than three months subsequently to the date of his reference.”

INDIAN MEDICAL CONGRESS.

The objects of this Congress, which will be held from December 24 to 29, 1894, are to bring together medical men from all parts of the Indian Empire to discuss Indian diseases, and to place on permanent record some of the work which is now lost to science for want of proper publication. The work of the Congress will be divided into the following sections:—1, Medicine and Pathology; 2, Surgery, including Ophthalmology; 3, Obstetrics, and Diseases of Women and Children; 4, Public Health; 5, Medico-Legal Medicine and Insanity; 6, Pharmacology, specially Indigenous Drugs. Although the Congress is primarily an Indian one, invitations have been sent to medical men in other countries, some of whom have already accepted, and it is believed that many more will come. A special committee has been formed to arrange for the accommodation of visitors and to provide for their comfort. The local secretaries of this committee are:—(1) Surgeon-Captain H. W. Pilgrim, General Hospital, Calcutta; (2) Dr. Prandham Bose, M.B., Calcutta Medical School, Calcutta, to whom, or to the honorary central secretaries, applications should be made for rooms. The price of accommodation in Calcutta may be taken from Rs. 7 to Rs. 14 a day for Europeans, and from Rs. 3 to Rs. 5 for Indians. Tickets of membership may be obtained from either the honorary central secretaries in Calcutta, or from the local secretaries, in the different parts of the Indian Empire. Members are requested to notify to the central secretaries, or to the local secretaries of their districts, their intention to read papers and the titles of the same, which should reach the central secretaries not later than October 15, 1894.

PROCEEDINGS UNDER THE PHARMACY ACTS.

The Manchester Evening News remarks that the Pharmaceutical Society is “doing good service to the community by suing unqualified persons who sell poisons. One of the greatest dangers to society is the case with which deadly drugs may be purchased, and a stricter enforcement of the Acts regulating their sale is highly desirable.”

INTERNATIONAL EXHIBITION AT ANVERS.

The tenth international exhibition of hygienic and alimentary products will be held at Anwerp during September under the auspices of the “Association internationale pour le progres de l’Hygiene.” The secretary of the executive committee is Mons. A. COPEMANS, pharmacien, Place de Meir, 85, Antwerp.
Transactions of the Pharmaceutical Society of Great Britain.

MEETING OF THE COUNCIL.

Wednesday, August 8, 1894.

Present—
MR. MICHAEL CARTEGHIERI, PRESIDENT,
MR. W. OWEN CROSS, VICE-PRESIDENT,
Messrs. Atkins, Bottle, Gosling, Grose, Hampson, Harrison, Johnston, Martin, Martindale, Newsholme, Schacht, and Storrs.

The minutes of the last meeting were read and confirmed.

The late Mr. Savage.

The President reported the receipt of a letter from Mr. W. W. Savage, Brighton, thanking the Council on his own and his mother’s behalf for the letter of sympathy which he—the President—had been authorised to write.

Mr. G. W. Sargent.

The President read letters which had been received by himself and the Vice-President from Mr. Sargent. They had come to the conclusion that these letters were unsatisfactory, and recommended that Mr. Sargent’s offer to resign his membership be accepted, and his name be removed from the roll of members. He would move a resolution to that effect.

The Vice-President seconded the motion, which was carried unanimously.

The Regulations of the Board of Examiners.

The President said the resolution passed at the last meeting had been submitted to the Boards of Examiners, and they had recommended certain alterations in the Regulations to the effect that in the practical examination in chemistry candidates should be familiar with the construction and use of the balances, and have a practical knowledge of the British and metric systems of weights and measures; but the Boards did not consider it desirable to require, in addition to the practical knowledge of the metric system now exacted for the chemistry part of the examination, a further practical examination in that system, dispensing, or an oral examination in posology. The President, in moving the reception and adoption of the report, and that the proposed alterations be approved by the Council, said he could now speak with certainty on a point as to which he was not absolutely sure at the last meeting, viz., that every candidate both in the north and south used the metric system of weights and measures in his daily work in chemistry, so that practically the suggestion of Mr. Martindale were already in operation. The Boards did not consider it desirable at present to examine in practical dispensing and posology in the metric system. They took the view that the requirements at present in force were quite sufficient. The members of the Board, in particular, were very strong on the point, and both Boards were agreed. Such a test could not be satisfactorily gone through without considerably more time being allowed for the examination, and it was felt that if a candidate could perform the weighing and measuring necessary for his chemical work, it would be very difficult to say that he was incompetent to dispense a prescription in which the same weights and measures were used. Both Boards were alive to the object which Mr. Martindale had in view, but they believed that even if dispensing in the metric system were included in the examinations, and the students were examined in posology in those weights, it would not unsettle what Mr. Martindale desired that, in fact, the Metric would then be the English system, and translate into the other; and that until, in fact, a large amount of practical work was done in dispensing in this system throughout the country, the candidates would never have that real practical acquaintance with the system which was aimed at, and that a mere examination would not be sufficient for that purpose. As regarded the safety of the public, the Boards were unanimous that the amount of knowledge exacted from candidates was sufficient to ensure this in any cases in which prescriptions in the metric system were presented.

Mr. Martindale said he was sorry the Boards of Examiners had taken this view of the subject. It seemed that though a knowledge of the metric system was required from the candidates, they were not to be trusted to use for practical dispensing a system which he hoped would come into use within the present generation. He feared that the matter would be put off for an indefinite time. He feared that, as happened in France, it would require some Imperial decree to enforce it, or there would be very little chance of the metric system being generally introduced. It was stated in France, during the time of Louis Philippe, that it was not the needs of commerce which opposed the complete introduction of the system, but the indolence of the people, and he was afraid that it was something of the same sort with British pharmacists and the Boards of Examiners. They feared they would have so much more work to do that they dared not face the subject. He was sorry for the result, for he feared it would delay the introduction of the metric system for an indefinite time.

The President said the Boards of Examiners had no fear of additional work for themselves, but they had to consider as practical men the additional work which would be thrown on the candidates, and far from regarding their powers under the Act, they could carry their requirements from time to time. They had made considerable progress during the last few years, and the principle of festina lente applied to examinations as well as other things. The motion was then put and carried.

Diplomas.

The undersigned, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:

Anthony, Everard Perleval.
Ashby, Charles Edmund.
Athey, George Hedley.
Batter, Ernest Charles.
Cowin, William Stephen.
Cox, Harry Bertrand.
Davies, Robert Fisher.
Dyson, Herbert.
Foden, Thomas Henry.
Ginns, Edmund William.
Gillitt, Albert Ambrose.
Greig, John.
Harvey, Thomas Featherstone.
Hayward, Walter Edwin.
Henry, Thomas Anderson.
Highfield, Henry.
Hill, Aubrey Thomas.
Jackson, Thomas.
Lander, Arthur.
Martin, George Hymers.
Maskew, William.
Mercer, Frank Norland.
Robertson, George Daniel.
St. Cyr, Etienne Laurence Nelvil.
Southall, Horace.
Turner, John William James.
Ward, Joseph William.
Williams, William.

ELECTION OF MEMBERS.

The following, having passed the Major examination, and tendered their subscriptions for the current year, were elected "Members" of the Society:

Pharmaceutical Chemists.
Ashby, Charles Edmund
Cowin, William Stephen
Cox, Harry Bertrand
Davies, Robert Fisher
Dysan, Herbert
Gamble, Frederic William
Gillitt, Albert Ambrose
Harvey, Thomas Featherstone
Henry, Thomas Anderson
Hill, Aubrey Thomas
Jackson, Thomas
Landor, Arthur
Martin, George Hymer
Maskew, William
Mercer, Frank Norland
Norman, Edwin
Robertson, George Daniel
St. Cyr, Etienne Laurence Nelvil
Southall, Horace.
Turner, John William James.

ELECTION OF ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:

Hughes, Thomas John
Lloyd, Henry Morgan
Scott, Henry Pile
Williams, Frederick

ELECTION OF ASSOCIATES.

The following, having passed the Minor examination, and tendered (or paid as Students) their subscriptions for the current year, were elected "Associates" of the Society:

Adams, William Wright
Ahler, Ernest
Allen, John Henry Stanley
Arendal, Edmund
Aves, Ernest Harold
Baker, William Charles
Berrill, Edith Annie
Bloor, Frederick Arthur
Blyth, Frederick
Bostock, John
Boyce, Herbert George
Brown, Harry Samuel
Breeze, John Soley
Burgess, Sydney Robert
Burnell, Benjamin Lawson
Barrows, Harry
Coleman, John Harold
Cooper, George Henry
Cundall, Thomas Bowser
Davies, David Evans
Delaney, Edwin Louis
Dawson, Frederick
Dickens, Charles Samson
Evans, Evan Castell
Flood, Fanny
Gaul, Ernest George
Harbin, George Albert
Harrar, Thomas
Hsekes, John William
Hendry, Fred Harry
Hick, Wm. Henry Henwood
Hirst, Edward
Holmes, John
Hoole, Herbert Edward
Hough, Thomas
Hughes, Job
King, Ebenezer Thomas
Knight, George Thomas
Lawson, Albert Edward
Lee, John Cuthbert
Lewis, David Evan
Male, Elliott Wm. Graves
Marsh, Alfred Edward
Mitchell, Donald
Murray, Alexander
Nicholls, Ralph
Oldham, Harry
Parker, Herbert Charles
Parry, Lewis
Perrett, Henry John
Pitt, Charles Frederick
Pott, Thomas Burbidge
Prior, James Siddall
Richards, Ernest
Shattock, John Bellist
Smedley, Walter Graham
Sonley, Walter
Sproston, Francis John
Stow, Norman Vincent
Strachan, Alfred Emes
Thorne, Alfred John
Townsend, William Alfred
Trease, Robert James
Vogt, George
War, George Stafford
Ware, Alan Henry
Wolstenholme, Austin Whitley
Young, James Clements

ELECTION OF STUDENTS.

The following, having passed the First examination, and tendered their subscriptions for the current year, were elected "Students" of the Society:

Agar, John Parrick
Atkins, William
Atkinson, Frederick
Ball, Ernest Harry
Bryan, David Allen
Cawthorne, Montague
Cowling, Ernest
Crane, William Thomas
Davies, William Osborne
Dawson, Frederick
Dock, Reginald
Dennis, James Edward
Dowling, Alfred
Duck, Frederick Edwin
Evans, Harry John
Glover, Charles Cuthbert
Graves, Alfred Ellis
Hillery, Henry Edgar
Knowles, Charles John
Little, William Penrice
Lucas, Alfred
Mckean, Donald Neil
Mitchell, Arthur
Orrell, William Herbert
Paterson, Arthur Colling

BARNS AND CASTLES.
Restoration to the Register.
The name of the following person was restored to the
Register of chemists and druggists:—
Samuel Henry Venables .... Gorleston, Suffolk.

This report was of the usual character, and recom-
mended various accounts for payment, also the pur-
chase of £100 Consols on the Benevolent Fund
account account.
The President (as Chairman of the Committee)
moved the adoption of the report, which he said
called for no special comment, either as regarded the
receipts or payments. The recommendation to invest
£100 on the Benevolent Fund account was one which
he quite concurred in, as he had often noticed that it
had a beneficial effect on the subscriptions.
The report was unanimously adopted.

The report of this Committee included recommenda-
tions of the following grants:—
£10 to the widow (44) of a former subscriber to the
Society. She had a grant of £15 in 1885, and one of
£5 in January, 1888, is recovering from a long illness,
and has two children of 11 and 8 years respectively
(Liverpool).
£20 to the widow (42) of an associate who subscribed
to the Fund. Since her husband’s death she has been a
lecturer and demonstrator in cookery, but has broken
down in health, and the application was on behalf of
her two girls, aged 7 and 12 respectively (London).
One other application had not been entertained.
The Vice-President, in formally moving the re-
ception and adoption of the report, said it contained
no special features, and it was unanimously adopted
without comment.

Report of the Library, Museum, School, and
House Committee.
Library.
The report of the Librarian had been received,
including the following particulars:—
June .... | Day .... 626 36 16 24
| Evening .... 229 19 6 11

June .... | 218 | 134 | 84 | 18s. 8d.

Donations to the Library had been announced
(Pharm. Jour., July 14, p. 34), and the Com-
mitee had directed that the usual letters of thanks
be sent to the respective donors.
The Committee had recommended that the under-
mentioned works be purchased:—

For the Library in London—
Frankland, Micro-organisms in water.
Chambers’ Encyclopaedia.
Quain, Dictionary of Medicine, 2nd ed.
For the Library in Edinburgh—
Quain, Dictionary of Medicine, 2nd ed.
Oliver, Systematic Botany.
Sawer, Odorographia, 2nd series.
Phillips, Materia Medica.
The Committee had also recommended that a new
book-case be erected in the west Library (old Council
room).
The Committee had further recommended that the
Librarian be authorised to attend the annual meeting
of the Library Association at Belfast in September.

Museum.
The Curator’s report had been received, and in-
cluded the following particulars:—
June .... | Morning 611 41 10 23
| Evening 88 12 1 3

Donations to the Museum had been announced
(Pharm. Jour., July 14, p. 34), and the Com-
mitee had directed that the usual letters of thanks
be sent to the respective donors.

The Curator had submitted a report of the first annual
meeting of the Museums Association, held in Dublin
on June 20.
The staff of the Society’s School had attended and
reported on the various classes.
The Committee recommended that the Library and
Museum in London and Edinburgh be closed in the
evening during August and September, also that the
Library and Museum in London be closed entirely
from September 1 to 14, and in Edinburgh from
August 1 to 15.
The Committee recommended that certain cleaning
and repairs be carried out during the vacation.
Also that the Inaugural Sessional meeting take
place on Wednesday, October 3, at 3 p.m.
A letter was read from Mr. E. F. Harrison, resigning
his position as assistant lecturer in chemistry. A
communication had also been received from Professor
Dunstan, pointing out the importance of having some
systematic and practical teaching in physics, and
suggesting that Mr. H. A. Dowett, B.Sc., be
appointed assistant lecturer in the place of Mr.
Harrison, and that Mr. Dowett should undertake a
course of instruction in physics and practical physics,
separate from the subject of chemistry.
The Committee recommended that the suggestion
be regarded as to the teaching of physics be adopted, and
that Mr. Dowett be appointed assistant lecturer in
chemistry during the ensuing season, with an annual
stipend of £50, he undertaking the instruction in
physics; and that £30 be granted for the purchase
of physical apparatus.
In consequence of the resignation of the present
lecture-room attendant, the Committee recommended
the appointment of a new lecture assistant, with a
stipend of £40 per annum.
The Committee having considered the communica-
tion from the Colonial Office concerning the new
post of Lecturer in Jamaica, recommended that the Pres-
ident be requested to call the attention of the Marquis of Ripon to clauses 7 and 25, of law 34 of
1894.
The President, in moving the reception and adop-
tion of the report, said the greater part of it was
merely formal, and called for no remark. The resignation of Mr. Harrison necessitated a new election, and
Professor Dunstan attended the Committee in persi
and explained that Mr. Jowett had done extremely good work in the Research Laboratory, and had been so industrious that he had passed his B.Sc. examination. He had filled up his spare time—which he got goodness only knew where—in such an acquisition of practical physics as was highly creditable to him. In these circumstances the Committee thought it desirable to utilise his services. They were not in a position to recommend the foundation of what was generally termed a physical laboratory, but they would place at the disposal of students one of the laboratories and the lecture room, and give them an opportunity of handling the apparatus and performing physical experiments. It was not intended that the office should be held for a definite time, but they desired to encourage young men to come forward and from time to time hold this office. The stipend would be nominal, but it would encourage capable and deserving men, like Mr. Jowett, to get on the scientific ladder, and become a credit to the school, as well as to themselves. As to the lecture-room attendant, they were not making a new appointment, but simply converting a weekly payment into an annual one; and they found a number of candidates for a post affording opportunities of gaining knowledge and of doing practical work. The fact that such knowledge could be acquired was proved in the case of Mr. Bodey, who, commencing his career at University College, Bristol, as a boy under Professor Ramsey, subsequently served under his successor, Mr. Sidney Young, and coming to them (the Pharmaceutical Society) when about twenty-one, at a small weekly stipend, had, through his industry and perseverance, now obtained a teachership of chemistry under the School Board in the North of London. This showed the work they were able to encourage, and also that they were ready to help in the advancement of deserving students.

Mr. Martinson having seconded the adoption of the report, it was put and unanimously carried.

GENERAL PURPOSES COMMITTEE.

The report of this Committee included the following reports on the Prize Examinations:

Practical Chemistry.

Professor Atfield had reported that there had been sixty-three students in this class, rather below the average of the last ten sessions. The records of the daily work and weekly revision classes showed that the session had been an average one as regards the general mental calibre of the students and the work done.

Chemistry.

Professor Dunstan had reported that there were six candidates for the prizes, all of whose papers were highly creditable, the lowest award being more than 50 per cent., the two Bell scholars heading the list.

Materia Medica.

Professor Greenish had reported the total number of entries as twenty-four, the average attendance being twenty. The general conduct of the class had been good, and the progress made above the average. Five students only competed for the prizes, but the work done was extremely satisfactory.

Pharmacy and Practical Pharmacy.

Mr. Ince reported that seven candidates had passed for the prize examination, and that the work and attendance during the summer term had been most satisfactory.

Botany.

Professor Green had reported that seven candidates competed for the prizes in this class, all of whom did well, and four particularly so.

Herbarium.

Professor Green had reported the receipt of two collections, one by Mr. John Wisharts, of Insh, and one by Mr. Charles Kent, of Brighton. He recommended the award of a bronze medal to the former and a certificate of honour to the latter.

Price Awards.

Acting on the foregoing reports, the Committee had recommended that the following awards be made:

Practical Chemistry.

Silver Medal Charles Edmund Ashby.

Certificate of Honour... Charles John Taylor.

Chemistry.

Silver Medal... Thomas Anderson Henry.

Certificate of Honour... Thomas Jackson.

Materia Medica.

Silver Medal... Charles John Taylor.

Certificate of Honour... Arthur Landey.

Pharmacy.

Silver Medal... Charles John Taylor.

Council Examination Prizes.

Messrs. D. B. Dott and J. Jack, who had been appointed to conduct this examination, had reported that fifteen candidates competed for these prizes, and made the following awards:

Pereira Medal (Silver); and Books value £5, presented by the late Thomas Hyde Hills.

Aubrey Thomas Hill.

Pharmaceutical Society's Medal (Silver); and Books value £3, presented by the late Thomas Hyde Hills.

Charles Edmund Ashby.

Pharmaceutical Society's Medal (Bronze); and Books value £2, presented by the late Thomas Hyde Hills.

Frederic William Gamble.

The following are the mottoes adopted by the fifteen candidates for the Council Prizes, and are arranged in order of merit:

THE JACOB BELL MEMORIAL SCHOLARSHIPS.

The examiners appointed to conduct the examination for the Jacob Bell Scholarships had reported that twenty-two candidates had competed for the scholarships at the following centres:

Aberdeen, 1; Birmingham, 2; Bristol, 1; Carlisle, 1; Edinburgh, 1; Leeds, 1; Liverpool, 3; London, 7; Newcastle, 1; Manchester, 2; Northampton, 1; York, 1.
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS.

The envelopes bearing the mottoes of the successful candidates had been opened by the Committee appointed to make the award, and had been found to contain the names of the following:

Harold Brown ........ Southport.
John Robert Walker ......... Cockermouth.

The Committee had awarded the Scholarships to Mr. Brown and Mr. Walker, subject to the approval of the Council.

The following are the mottoes of the other competitors, placed in order of merit:

3, Nil desperandum (No. 1); 4, For God's sake; 5, Spero magooper; 6, In medias res; 7, Neutral; 8, Time flies; 9, Ego and Perseverance, equal; 10, "979"; 11, Dum spiro spero (No. 1); 12, Homo Latinissimus; 13, L'union fait la force; 14, Mente Manuque; 15, Cogito ergo sum; 16, Dum spiro spero (No. 2); 17, Nothing succeeds like success; 18, For God and country; 19, Ne cede malis; 20, Nulla dies sine linea; 21, Nil desperandum (No. 2).

MANCHESTER PHARMACEUTICAL ASSOCIATION SCHOLARSHIP.

The Committee reported that one candidate sat for the examination for this Scholarship, but that he had failed to obtain the standard of marks entitling him to the award of the Scholarship.

REDWOOD SCHOLARSHIP.

The President reported that the Research Committee had three applications for the Redwood Scholarship, and had suggested that the Scholarship be awarded to Mr. T. A. Henry, one of the Bell scholars of the present year. The Committee recommended that this suggestion be adopted.

The President moved the adoption of this portion of the report, and the consequent award of the prizes.

The resolution was carried unanimously.

A resolution was also passed authorising the payment of £45 to Mr. Tickle to enable him to continue his attendance in the Research Laboratory another year.

The President said the report of the Research Committee was made on the preceding evening to the General Purposes Committee, and he had also had an opportunity of seeing the report of the Examiners in the Manchester Pharmaceutical Association Scholarship. Finding the Examiners were not able to award the Scholarship, the Council could not do otherwise than accept the report, but he had communicated with Mr. Benger and Mr. Woolley, the President of the Association, and they had in turn communicated with the founder of the Scholarship, and they concurred in the suggestion that the money, which would otherwise be lying idle, should be allowed to Mr. Tickle to enable him to continue his attendance in the Research Laboratory for another session. It would be some gratification to those gentlemen to know that their similar action last year, when the money was allotted to Mr. Jowett, had been productive of good results, that gentleman being now appointed an assistant lecturer in the Society's School, especially as Mr. Jowett came from the district in which the money was raised.

Votes of thanks were unanimously passed to Messrs. Gerrard, White, and Pinches for conducting the Jacob Bell Scholarship examination, and to Messrs. Dott and Jack for conducting the Council Prize examination.

CONFERENCE OF LIBRARIANS.

The President said that a letter had been received from Mr. Macalister, hon. sec. of the Library Association, announcing the approaching annual meeting at Belfast, to be presided over by Lord Dufferin, and saying he believed it would be one of the most successful and practical meetings yet held; also inviting the Council to nominate delegates to attend the meeting. Their librarian (Mr. Knapman), the President added, would attend, and he would suggest that he be appointed a delegate. He did not know whether Mr. Atkins or any other gentleman interested in libraries would like to be appointed also. He doubt it would be an excellent meeting, and Irish hospitality was proverbial.

Mr. Atkins was sorry he could not see his way to attend the meeting; otherwise he should have been glad to do so.

Mr. Knapman was accordingly appointed a delegate to attend the Conference.

THE PHARMACY BILL.

The President also announced the receipt of a letter from Mr. Cox, hon. sec. of the Three Towns and District Chemists' Association, enclosing a resolution passed on July 12 in support of the Pharmacy Bill recently drafted, and also thanking the Council for their donation recently made to the Society.

CARBOLIC ACID AS A POISON.

The President likewise received a letter from Mr. Sidney Taylor, Deputy Coroner for Buxton, enclosing the recommendation of a jury, at a recent inquest over which he had presided, that carbolic acid be scheduled as a poison. The President added that he would propose that the Secretary be instructed to write to the Deputy Coroner asking him to forward the recommendation to the Privy Council, and as it was agreed to.

THE HOLIDAYS.

The President announced that the Council would not meet in September, the next meeting being held on the 3rd of October, and at three o'clock in the afternoon of that day, following the meeting of the Council, the inaugural address would be delivered.

The Council then went into committee, as usual, to consider the legal portion of the report of the General Purposes Committee. This included the monthly letter from the solicitor as to the progress of cases placed in his hands.

A large number of fresh cases of infringement of the Pharmacy Acts were reported to the Committee, and in each case proceedings were recommended. On resuming, the report and recommendations were adopted, and a resolution was passed authorising proceedings against the persons named in the resolution.
British Pharmaceutical Conference.

MEETING AT OXFORD.
FIRST DAY’S PROCEEDINGS.
(Continued from p. 110).

READING OF PAPERS.
The reading of papers was then proceeded with, the first two being considered together.

NOTE ON THE STABILITY OF THE ALKALOIDAL TINCTURES.

BY H. H. PARK AND E. WRIGHT, F.C.S.,
Pharmaceutical Chemists.

The question of the stability or otherwise of galenical preparations like tinctures is of considerable importance from a medical and pharmaceutical standpoint, because it is evident that in so far as such preparations are liable to undergo alteration in composition, either through the separating out of any of the principal constituents, or through changes taking place in the characters and properties of any of the active principles, by so much will the preparations themselves be rendered uncertain in strength and, consequently, unreliable in effect. The question assumes an added importance on account of the present disposition of opinion in favour of standardisation of preparations; and still more so in view of the fact that it is more than probable that the publication of the forthcoming edition of the British Pharmacopoeia will witness a considerable extension in the application of the principle of standardisation to preparations of potent drugs.

Now, if it were proved impossible to keep a preparation up to standard strength after being standardised, this fact would in itself constitute a great, if not an insuperable barrier in the way of carrying out any such system of standardisation as we have advocated for several years past. During the progress of our work on tinctures we therefore took the precaution to preserve specimens of each of the tinctures operated upon, intending, as soon as time and oppor-

</table>
tunity would allow, to turn our attention to the ques-
tion as to whether or not those tinctures, the active
principles of which are capable of ready and accurate
determination, suffered any diminution in strength
when kept for a length of time. We may infer that,
theoretically, the results of this inquiry might tend to
throw light upon the same question in its application
to other tinctures not brought under examination, or
at any rate that they might not be without interest in
their bearing upon that point. All the tinctures
examined were kept for a long period, in the case of the
majority of them for a space of two or three
years. The processes employed for the determination
of the alkaloids have been precisely the same as those
originally followed, and will be found published in the
individual papers, references to which are given in the
"Year-Books" for 1890-93.

The results obtained prove that the strength of these
tinctures, so far as can be judged from the
determination of their alkaloidal constituents, remains
approximately the same for a considerable length of
time, and it may fairly be assumed that when preserved
under normal conditions, such preparations remain
constant in composition. The only instances in which any
notable loss of alkaloid is apparent are those of the
tinctures of cinchona and green hellebore; and this loss
is doubtless due to the mechanical carrying out of
solution of traces of alkaloid by deposited resins
and extractive matter. The average loss in the most
extreme cases that of the tincture of green hellebore,
does not amount to 5 per cent. of the alkaloid origin-
ally present.

GRAMMETRIC AND VOLUMETRIC METHODS FOR
THE DETERMINATION OF THE ALKALOIDS IN
ALKALOIDAL TINCTURES.

BY H. P. HARRIS AND R. WRIGHT,
Pharmaceutical Chemists.

Probably the first systematic attempt to devise a
method for the approximate determination of the
alkaloids in galenical preparations was made by A. B.
Hawryluk ("Amer. Journ. Pharm.," Dec., 1886, and Jan.,
1887), who recommended for that purpose the titration
of acidulated solutions of the crude alkaloids with
Mayer's reagent. This process was found to have
many disadvantages, and Lyons himself has admitted
that the results obtained by it have at best only an
approximate value. The chief drawback of the method
was that the amount of the volumetric solutions
used up varies with the acidity of the alkaloidal
solution, the volume of the liquid, and the amount of
alkaloid present. To which must be added that most
of the precipitates produced are also soluble in the
mother liquor, and hence it is necessary to make a
correction for the solubility of the alkaloidal precipi-
tate. These facts have served to bring the method of
titration by Mayer's solution into disrepute, and
although in the hands of an analyst accustomed to
work with it the process may be capable of yielding
fairly accurate results, it is impossible that the use of
such a process will ever become general.

A gravimetric process for the determination of the alkaloids in certain extracts and tinctures was subsequently
proposed by J. U. Lloyd ('Proc. Amer. Pharm. Assoc.,'
1891). This consists in mixing a measured volume of
the preparation to be assayed with ferric chloride,
adding to the mixture a sufficient quantity of sodium
bicarbonate to precipitate the alkaloids, then extracting the alkaloid with chloroform. In some cases a process of
purification was recommended, which consisted in
shaking out the alkaloids with acidulated water, ren-
dering the solution alkaline, and extracting with
chloroform. Lloyd's assay process was very severely
criticised by J. B. Nagelvoort, and there is no doubt
that the figures obtained by this process are liable to
be as much below the mark as those yielded by that
t of Lyons are above it.

In 1889 a series of papers on tinctures was published
by F. W. Fletcher ('Chemist and Druggist,' January,
1889), in which definite proposals were made for
fixing the minimum standards of strength for tinctures
containing alkaloids, and processes for the isolation
and gravimetric determination of the alkaloids were
given.

A. H. Allen, in his "Handbook of Commercial Organic
Analyses" (2nd edition, vol. II, p. 148), has recommended a somewhat similar method for the isolation
of the alkaloid, obtained by shaking out, being dissolved
in ether or chloroform and the solution titrated with
HCl, methyl orange being used as indicator; and in
a paper on neutrality, read before the London
Chemists' Assistants' Association ('Pharm. Journ.,'
xxii., 1774), also gave a useful table, showing the
more important alkaloids towards methyl orange, phenol-phthalein, and litmus.

The subject of the titration of alkaloids has also
been dealt with by R. A. Cripps ('Pharm. Journ.,'
vol. xxii., p. 511), who, in a valuable contribution to
the literature of the subject, has shown how, by the
aid of these indicators, phenol, methyl blue, gallein,
etc., minute quantities of alkaloids can readily
be determined. In a note published in the American
Pharmaceutical Review, November, 1892, Professor
C. Caspary maintained that the alkaloidal residues
yielded by gravimetric methods invariably contained
from 10 per cent. of the marked superiority of volumetric processes of deter-
mination. He advocated a process consisting in the sol-
tion of the crude alkaloid in excess of HCI, and titra-
ting back with alkali, using Brazil wood as indi-
cator. Lastly, in a paper read before the American
Pharmaceutical Association last year, entitled "The Value of Titration with Volumetric Solution as
Means of Assaying Drugs and Galenical Preparations," Messrs. Caspary and Dohme have claimed to show
that the determination of alkaloids in galenical prepa-
ations may be effected more accurately by titration
than by the usual plan of weighing.

During the course of our work on the subject we
have employed gravimetric processes of determination
almost exclusively, it appeared to us absolutely necessary
to test the conclusions advanced by Caspary and Dohme,
in order to ascertain whether they had any foundation
in fact. With this object in view, each of the alka-
loidal tinctures previously submitted to examination
was prepared in quantity sufficient to admit of the
determination of the alkaloids being carried out by the
following processes:

1. Two gravimetric determinations by methods
described in our notes on tinctures.
2. The tincture was evaporated, the residual liquor
rendered alkaline, and the alkaloid extracted
with chloroform. Except in the cases of veratrum,
lollipop, and colchicum, the alkaloid was once
purified by shaking out with acidulated water,
rendering the solution alkaline, and again extract-
ing with chloroform. The chloroformic solution
was then washed with a little distilled water
before being titrated. When ammonium was used
as a precipitant of the alkaloid the washing was
repeated until the water, on separation, ceased
to become pink on addition of phenol-phthalein.
The chloroformic solution thus obtained was
utilised for the direct titration of the alkaloids with
HCl, methyl orange, iodocaine, and phlorin
being used as indicators in the separate experi-
mental work.
ments. In using methyl orange, a little distilled water is added along with two drops of the indicator; but with iodocine or phloxine a single drop of a $\frac{1}{20}$ solution is sufficient, and this is shaken up with the chloriform solution until the chloriform has become distinctly coloured. The indication of the end of the reaction is in the case of methyl orange the appearance of a slight pink colour in the aqueous layer, and where iodocine or phloxine is employed the decolorisation by the chloriform marks the end of the reaction.

3. The alkali, for the use of the gravimetric process was dissolved in a calculated excess of standard acid (usually 4 or 5 C.c.), the indicator added, followed by the addition of standard Ba$\text{ZnO}$ until the neutral point was reached. These determinations are preferably made in a white speckless dish in which the alkali has previously been obtained, as slight changes in colour are thus more easily recognised.

The indicators used were methyl orange and Brazil wood, supplemented where the volume of the tincture available would allow by iodocine and phloxine. In this case the indication of the end of the reaction, when methyl orange is employed is the development of the pink tint, and with Brazil wood the production of a purple colour. In the employment of iodocine and phloxine as indicators, except in direct titration, we have followed the plan recommended by Cripps in the paper referred to above, of adding to the acid alkaloidal solution sufficient neutral ether to leave a distinct supernatant layer when shaken up with the solution. The indication of the end of the reaction is the production of a pink tint in the lower layer. In the determinations, the results of which are recorded in the table, N hydrochloric acid has been employed, as an acid of this strength will be found generally suitable for use in determining alkaloidal residues from tinctures. A standard acid of this strength will also keep indefinitely. Of the alkaloids, barium hydrate is undoubtedly by far the most suitable, both because it gives a quicker reaction than potassium or sodium hydrate, and also because the absorption of carbon dioxide is soon evidenced by the turbidity of the solution. The exact strength of the solution employed is not very critical, so long as its value in terms of the standard acid is known. The facility with which it absorbs carbon dioxide from the air, it is necessary to ascertain its neutralising power before each determination. It is, perhaps, not advisable to work with a stronger solution than one of $\frac{1}{20}$ strength. Each C.c. of such a solution will contain nearly 0.0171 Gm.

Be$\text{ZnO}$, and will neutralise 0.4 C.c. HCl.

The following were the indicators used:—

Methyl Orange.—A tincture containing 1 grain of methyl orange dissolved in a fluid ounce of proof spirit.

Brazil Wood.—The U.S.P. test solution. This is made by boiling 50 grammes finely cut Brazil wood with 100 C.c. distilled water for half an hour, replacing the water lost from time to time. The mixture is allowed to cool, the liquor strained off, water added to 100 C.c. and a further addition made of 25 C.c. alcohol and the whole filtered.

Iodocine and Phloxine.—An aqueous solution containing 1 part in 1000 fluid parts.

The following is the list of the equivalents from which the results recorded in the table have been calculated.

</table>

In the case of cinchona, nux vomica, and veratrum the equivalents are calculated by taking the mean of the molecular weights of the chief alkaloids.

The results obtained are embodied in the accompanying table (see page 126).

Notes on results.

1. Volumetric methods appear useless for the determination of the alkaloids of aconite, the large proportion of aconine present (equivalent 0.2715) making the readings too high.

2. They are also useless in the case of preparations of colchicum, which appears to contain a small percentage of an alkaloid having definite basic properties, probably colchicine, with a considerable proportion of some other possibly equally active but chemically indifferent substance.

3. Gelsemium contains two alkaloids, gelsemine and gelseminine, the former crystalline, the latter amorphous. Gelseminine is said to be present in the drug only in small proportion. The formula of gelsemine has been given by Gerrard as C$_{34}$H$_{43}$N$_{4}$O$_{7}$, by Bonnenschein as C$_{40}$H$_{43}$N$_{4}$O$_{7}$, while the most recent researches of L. Spiegel cause him to hesitate between the formula given by Gerrard and the alternative formula C$_{34}$H$_{43}$N$_{4}$O$_{7}$, with which some of the results of his experiments agree better.

The figures given in the table are calculated upon the basis of the alternative formula of Spiegel.

4. The titration of the cinchona bases is attended with great difficulty, owing to the end reaction being almost unobservable. With extreme care fairly accurate results may be obtained, but our experience with this tincture has been such as to cause us unhastily to condemn the application of any volumetric process to the assay of this tincture. In several instances the results indicated by titration were exactly twice as great as those obtained by weighing.

5. The volumetric determinations of the alkaloids in the tinctures of veratrum examined yielded results approximating very fairly to those of the gravimetrical determination, but the formula weights of the alkaloids of veratrum differ so widely that such comparative accuracy could by no means be generally relied upon.

6. The tinctures which lend themselves most readily to determination by titration are those of belladonna, henbane, stramonium, conium, jaborandi, lobelia. Nux vomica and opium (for morphine). As a general process the following method of determination is put forward with some degree of confidence as one which would, we think, be found in some cases almost equally reliable and somewhat more expeditious than gravimetric processes. "From 25 to 50 C.c. (in the case of hyoscyamus 100 C.c.) of the tincture to be determined is introduced into a clean dish and evaporated over a water-bath, with addition of water if necessary, until all alcohol has been driven off. The residual extract is acidified and filtered through cotton wool into a stoppered separator, the dish and filter being

*For the opium determinations a solution of anhydrous morphine obtained in estimating the tincture by the B.P. process was employed; this was dissolved in excess of $\text{HCl}_{\text{aq}}$, washed with acetylated water, and the washings added to the contents of the separator. The acid liquid is then shaken with two successive portions of chloroform and the latter drawn off. The separated chloroform is washed with a little acetylated water, and after separation the latter is removed and added to the contents of the separator. The liquid in the separator is then made alkaline and the alkaloids taken out by shaking with three successive small quantities of chloroform. The chloroformic solutions are drawn off into a cylinder provided with a good cork, and when ammonia has been employed as the precipitant, washed with distilled water until the washings cease to give a pink tint with phenol-phtalein. A drop of $\text{Iodine}_{\text{solv}}$ iodine solution is then added, and the whole well shaken until the chloroform is distinctly tinted, and then carefully run in from a buret graduated to tenths of a c.c., the mixture being well shaken after each addition of the acid until the colour is discharged from the chloroform. The reading is now taken, and the amount of alkaloid calculated from the proper equivalent. This process is not applicable to tincture of lobelia, the alkaloids from which must be obtained in ethereal or chloroformic solution by the process published in the *Chemist and Druggist*, vol. lxxii., p. 464. It is only necessary to say, in conclusion, that while we admit that the application of volumetric methods of determination to the alkaloids obtained from tinctures is sometimes useful as affording a check upon the results obtained by gravimetric methods, we still maintain that the results yielded by the latter are, in anything, the more reliable of the two. And while the former may be more in favour with scientific chemists and thoroughly competent analysts, the latter are the processes for the practical pharmacist.*

The President said these papers were very valuable, but would have been much more so if the authors had prepared large diagrams containing the tables referred to.

Mr. Wright said he took the trouble to do this last year, and was rather surprised to find that no one attempted to make any use of the diagrams, which he had spent many hours in preparing.

Mr. Umney said there were three things quite different, that this paper could not be discussed, because covered such a vast field that it was impossible to take it in on merely hearing it, and though he sympathised with Mr. Wright, he must say that the tables would have been of some service in following the paper. In the next place, pharmacists throughout the world were very much indebted to the authors for having cleared up matters which had been in doubt for years. They had been using tinctures of emmena, henbane, colchicum, cinchona, etc., with being at all sure whether they were at all uniform in strength, or whether their potency could be accurately determined, but they had now, as the result of an immense amount of experiment, some definite information on these matters. Thirdly, they bad
definite opinion that at least ten or a dozen of these tinctures could be standardised, and he hoped when the new pharmacopoeia came out, the leading tinctures which physicians were accustomed to prescribe would be put in a standardised form, so as to be at any rate a little in advance of the pharmacy of the last half century.

Mr. Martindale also spoke of the great importance and interest of these papers, especially as regarded the keeping properties of tinctures. As far as he gathered there were two which did lose a notable amount of their properties on keeping, one of which he thought was cinchona.

Mr. Wright said cinchona was fairly stable, the two he specially mentioned were cinchona and veratrum.

Mr. Martindale said he was going to suggest that in those cases an acetic tincture might be made. In his opinion, if that were found to be the case, the alkaloid might be fixed by acetic acid, but that might not apply to cinchona. He was less certain about the tincture he had found that, as Mr. Unney once said, he belted and that he could see many, and he would add, in what could be crystallised; or if the percentage could not be given in crystallisable salts or alkaloids—as in the case of jaborandil, which contained a liquid alkaloid, likely to be contaminated by the so-called principle jabordine, which might itself be a derivative from the decomposition of the alkaloid—yet at all events the crystallisable salt, the nitrate, was insoluble in alcohol, and a process might be devised for getting that crystallisable body in a definite condition and weighing it, if the percentage of liquid alkaloid were at all doubtful.

Mr. Groves said he would like to know the exact conditions under which these tinctures were kept. He would also remark that many of these drugs contained more than one alkaloid, and that these varied in strength, and some had no activity at all, so that the mere determination of the total alkaloids, though useful for some purposes, did not indicate the activity of the drug.

Mr. Parker asked if any investigation of vinum coelchi had been made by the authors.

Mr. Moss agreed with the President as to the great importance of having diagrams of the tables in such papers; they assisted the mind, and obviated a great deal of work in the memory in endeavouring to follow the paper. Even if the diagrams were not referred to at all, he had no doubt they were of great assistance. Mr. Martindale had drawn attention to the great constancy of these tinctures after being kept for two or three years, which was very striking. This, he thought, only referred to the total amount of alkaloids, whether determined gravimetrically or volumetrically, and did not touch the point raised by Mr. Groves as to their activity. Another point to which his attention was directed was the different results obtained with regard to tincture of coelochrom by the two methods. In the first paper he thought the final strength of the tincture of colchicum, No. 1, as about twice that of No. 2; and although the two tinctures remained constant, he thought the treatment between the two strengths suggested a difference in the character of the drug from which they were prepared; probably they were from different samples, or from different sources. He wished to add his testimony to the pains the authors must have taken over a long and laborious subject, and Mr. Acock asked if the tinctures on re-examination were found pure and bright. They all knew that, if too often a deposit in a tincture some time after was prepared, and the question of what was contained in that deposit might be cleared up if it were ascertained that the alkaloidal tinctures remained bright, or if a loss of alkaloid accompanied the appearance of sediment.

Mr. Symes thought, on the whole, the results adduced seemed to show that the volumetric method was reliable, and might even be of value in checking the gravimetric method.

Mr. Lloyd Williams said in many cases one could not determine a tincture by the volumetric method, because the actual composition of the salts was unknown, and the probable composition varied so much that there was no absolute certainty about the method, and he preferred the gravimetric. In that there was something which could be seen, and was in a state of tolerable purity. In the absence of either condition, or possibly both, one could determine the absolute quantity of material present, but could certainly get results which, if the investigator used the same methods, were comparable amongst themselves. In making volumetric determinations of tinctures he had found that extreme difficulties arose in dealing with different samples and that he always standardised against a practically pure salt of known composition, and always kept to its standard of composition.

Mr. Conboy said he had made a great admiration for the immense amount of work which the authors must have put through, and how very valuable it would be after going through this stupendous labour they found, on re-examination of the tinctures, that they practically retained their full strength. He would suggest that if at any future occasion the tests were repeated, it would be well to test the deposits also in the case of cinchona and veratrum. They might then be able to say definitely whether the deficiency was due to decomposition or dissipation.

Mr. Gerhard was very pleased to find that the tinctures maintained their character so well, as it would tend to give the medical profession confidence in prescribing them. In many cases they possessed advantages over the pure alkaloidal preparations, in that they contained the constituents of the drug in the natural state of combination. With regard to the comparative merits of the gravimetric and volumetric methods, he was rather in favour of the latter, for this reason: In working, as the authors had done, on a quantity of material, taking 25 or 50 c.c. of tincture and evaporating to an extract, it required very careful work indeed to deal accurately with such a small quantity. He knew, from some amount of experience, what difficulties occurred in getting the pure residue to titrate from, and unless they titrated the residue side by side with the pure base, as suggested by Mr. Williams, he felt sure they would include in the residue some foreign bodies. It was not easy to get an absolutely pure residue from such small quantities, and if it contained a little resinous or charged matter of some description, and you dissolved it in a solvent, treated it, and then neutralised it, what you neutralised was only the alkaloid, and what you weighed might be something other than the base.

He would ask the authors whether they weighed or measured the tincture previously to the examination, because the difference in the two processes might account for slight differences in the results. They had taken some of the different figures obtained in the case of geelsemine to those obtained by himself, but he thought that might be fairly accounted for by the fact that they were working with small quantities, whilst he worked with as much as 1 oz. of material, and even then he found it exceedingly difficult to get the alkaloid in a pure state. He could easily imagine that with the small quantities they used there would be a difference in the figures.

The President said the authors should like to emphasise what had been said as to the gratitude they all owed to Messrs. Farr and Wright for their work, especially as it was work which did not appeal to everybody, for
it required great patience and determination to go on making experiment after experiment without obtaining any brilliant results. The first paper on the subject of the alkaloidal tintures was very valuable; but with regard to the second one, he did not think the results of the experiments altogether warranted the strong condemnation of the volumetric method of determination for cinchona. In the first case the alkaloid by the gravimetric method gave 0.74, and by the other method 0.114 and 0.115; in the second experiment by the gravimetric method was 0.57 and by the same reagents 0.577 and 0.586, so that it looked as if there were something wrong somewhere. In the first experiment the result by the volumetric method was nearly double, and in the other they were nearly identical. That could hardly be taken as a conclusive experiment. He agreed with Mr. Groves that it was not easy to fix the clinical value of a tincture by the amount of one alkaloid present. He was not quite sure that they could be perfectly certain of having that alkaloid in a pure form, or that they always knew which was the important one. In the case of the cinchonin there was a difficulty in knowing exactly what it was, and in the case of gelouse the authors themselves said there was a considerable difficulty in this matter. But this did not detract from the value of the investigation as far as it went.

Mr. Wright, in reply, said he quite agreed that it was impossible to ascertain the exact clinical value of a tincture by determining the alkaloids contained; all they contended for was that if you knew the exact amount of alkaloid it would yield, and fixed a minimum standard of alkaloid for it, there was a far better guarantee for the clinical value than under the Haphazard method of making tintures which had been followed up to the present time. With regard to the comparative value of gravimetric and volumetric processes for the determination of alkaloids and alkaloidal residues, he was inclined to agree with Mr. Gerrard, especially in the case of geloseine. In the case of several tinctures they employed the same method, and got some very peculiar results, first of all an alkaloid which had exactly the saturate base of Mr. Gerrard's geloseine, and on adding chloroform after exhausting the tincture with ether got a further quantity which had a saturating power considerably in excess of that obtained by using ether. That went to prove that there were two separate alkaloids in geloseine, one having the molecular form stated by Gerrard, and another having a lower molecular weight. This was a subject which required further investigation, and he had, in fact, commenced upon it. Mr. Martindale suggested the use of acetic acid in making tincture of cinchona to fix the alkaloid, but in cinchona the alkaloid was already fixed. In fact, in his own opinion, this was one of the most stable tinctures, although the alkaloid was said to be volatile. He believed it existed in combination with some organic acid. The tinctures were not kept in any special vessels; some were in full bottles, some partially so, many in the laboratory, some in the cellar—no special precautions were taken. With regard to colchicum wine they had made no special investigation, but he recently ascertained for a medical man that the tincture of colchicum was slightly stronger than the Hislop contained rather more of the same principle; probably the tannin in the wine fixed some of the alkaloid. With regard to Mr. Moss's remark on the subject of the diagrams last year, he was glad to find that they produced more impression on friends at a distance than they appeared to do on those present. Generally speaking the tinctures were pure and bright; in the case of cinchona and veratrum there was a deposit, and no doubt the slight loss of alkaloid in those cases was due to the fact that some was carried out of solution by the depositing matter. It was inclined on the whole to maintain that the gravimetric process was more reliable than the volumetric, with this caution, that there was, in one or two cases, the greatest difficulty in getting rid of the last trace of residuary matter. In the case of geloseine there was some colouring matter present which they had to devise a special process for getting rid of; it was certainly not an acid residuum, and there were two other tintures in which the same difficulty occurred. In veratrum the residuary matter clung persistently to the alkaloid, and if further work showed that the volumetric method was reliable in this case, he should admit that it had the advantage. The same with regard to lobelia; the alkaloid there was combined in some very peculiar manner with some other substance, and it was very difficult to get the alkaloid. The advantage of the gravimetric method was that when you saw a substance you knew you had it, but, on the other hand, when you weighed, you weighed everything you had, and if there were any foreign matter present that was included. They had done more with the volumetric method of Cinchona, because they obtained results just double those obtained in the other way.

(To be continued.)

Parliamentary and Law Proceedings.

PROCEEDINGS IN THE COURT OF CHANCERY.

REVOCATION OF A PATENT FOR A MEDICINAL PREPARATION.

In the Chancery Division of the High Court of Justice, on Tuesday, August 7, Mr. Justice Norden held a petition presented by the Pharmaceutical Society for the revocation of Patent No. 20,062, of 1803, the "complete specification" of which is as follows:

Complete Specification.

An Improved Medicinal Preparation for the Cure of Indigestion and like Complaints.

I. Elizabeth Vaisey, of Thames Villa, Shillingford, Wallingford, in the County of Berkshire, do hereby declare the nature of this invention, and in manner the same is to be performed, to be particularly described and ascertained in and by the following statement:

This invention relates to an improved medicinal preparation for the cure of indigestion and like complaints, and consists, for example, for a two ounce bottle, as follows:

Diluted prussic acid ... 1 drachm.
Bicarbonate of potash ... 1 drachm.
Compound tincture of lavender ... 2 drachms.
Distilled water, add to make up ... 2 ounces.

These should be well mixed together, and two spoonfuls of the preparation taken in water.

Having now particularly described and ascertained the nature of my said invention, and in manner the same is to be performed, I declare that what I claim is:

A medicinal preparation consisting of the above-mentioned ingredients combined in or about the proportion stated.

Dated this 24th day of October, 1803.
Mr. R. Wallace appeared for the petitioners, and said: If your Lordship please, this is a petition for the revocation of Letters Patent, presented under the 26th section of the Patent Designs and Trade Marks Act, 1883. The leave of the Attorney-General has been obtained in this matter. The Pharmaceutical Society of Great Britain are the petitioners.

Mr. Justice North: Wait a moment. I do not quite understand how you come under the 26th section. It says it may be presented—

Mr. Wallace: By the following persons, by the Attorney-General in England and Ireland, or by the Lord Advocate in Scotland.

Mr. Justice North: Or by any person authorised by the Attorney-General in England or Ireland.

Mr. Wallace: We are authorised by the Attorney-General to present the petition. I appear for the Pharmaceutical Society of Great Britain. That is a society incorporated by Royal Charter and by Act of Parliament, 15 and 16 Vict., cap. 56. Its object is the protection of chemists and druggists by the Act, and by an Act of 1888 it was also entrusted with certain duties to protect the public with regard to the sale of medicines. Now, my Lord, section 16 of the Pharmacy Act says that no medicines which contain shall interfere with the business of any legally qualified apothecary or any member of the Royal College of Veterinary Surgeons, nor with the making and dealing in patent medicines; and it is because of that section that we come before your Lordship, and because of a decision in the first Queen's Bench Division, 1893, p. 668, the case being the Pharmaceutical Society v. Piper.

Mr. Justice North: You have not told me what you want to do. To revoke a patent granted to whom?

Mr. Wallace: A patent has been granted to Elizabeth Vaisey for a poison, because of this decision, under which it was held that the Pharmaceutical Society had not power to restrain the sale of poisons when a patent had been granted. That was under the section I have just read. The consequence was, people were taken out on the wrong kind of grounds. The result was to prevent the Pharmaceutical Society protecting the public under the Act of Parliament. A great many invalid patents have been taken out. This is about the fifth or sixth I have applied to revoke under the same conditions, and the respondent has never appeared.

Mr. Justice North: What case is it you refer to?

Mr. Wallace: The Pharmaceutical Society v. Piper.

That was the case of a preparation which contained morphine and other poisons.

Mr. Justice North: It is not lawful to retail or dispense poisons unless the man is a pharmaceutical chemist or a chemist with a licence.

Mr. Wallace: Yes, my Lord. Then the head-note to that case says "That the prohibition in the Act against the sale of poisons by other than registered chemists was not confined to the sale of scheduled poisons in their simple state, or of the preparations of such poisons, but extended to the sale of a compound containing a scheduled poison as one of its ingredients; and further, that the exception in section 16 in favour of patent medicines extended only to medicines which were the subject of Letters Patent, and not to proprietary medicines." The Society cannot prove that this case has been the subject of Letters Patent granted; that takes the vendor of the medicine out of the Act. They take out these worthless patents with the object of preventing the Pharmaceutical Society proceeding against them, under their Charter and under the Act. This patent is No. 20,082 of 1889, and is for an improved medicinal preparation for the cure of indigestion and like complaints, and it says "The invention relates to an improved medicinal pre-
made, of course that new compound would be subject
matter for a patent, but here the bicarbonate of
potash is only the base for holding the prussic acid,
and the other ingredients are the flavoured
mixture, and then there is only distilled water besides.
Practically it is for prussic acid pure and simple,
which is a well-known drug, and is prescribed by
physicians. Now, my Lord, the petition recites the
facts I have told your Lordship, but we have no
affidavit verifying it, because we were not able to
find the President of the Pharmaceutical Society on
Saturday, but we will verify the petition.
Mr. Justice North: Is he the only person com-
petent to verify it?
Mr. Wallace: He has gone into the whole matter,
and he made the declaration which was before the
Attorney-General. In fact, my Lord, all we have to
do is to make the declaration into an affidavit. The
Patent Office takes it here with this declaration
which was before the Attorney-General. We did not
know until yesterday that the revocation would be
consented to, but no one is here to consent.
Mr. Justice North: Well, let us go on with the
petition.
Mr. Wallace: Well, my Lord, the petition recites
the facts as to the Charter being granted and so on,
and then it recites what the patent is for and the
claim, and in the fourth paragraph it says, "The use
of dilute prussic acid—"
Mr. Justice North: I was looking at the sixth para-
graph.
Mr. Wallace: Yes, my Lord. "The said Eliza-
abeth Valsey has failed in the said specification to de-
clarate the nature of her invention, and has not stated
sufficiently the proportion of the various ingredients
set out in the complete specification which it is neces-
sary to use in order to carry out her alleged inven-
tion. It is stated in the said specification that one
of the component parts is dilute prussic acid, but
no direction is given as to the strength of the prussic
acid which is to be used. In the claim the words
'Combined in or about the proportion stated' appear.
Your petitioners submit that the statements are
vague and misleading, and impose upon persons who
may desire to use the said invention the necessity of
ascertaining by trial and experiment what is the
proper strength of the acid to be used. Further, to
ascertain by trial and experiment what is the
exact proportion of the various compounds to be
used. For the above and other reasons your peti-
tioners submit that the alleged invention claimed is
one for which Letters Patent ought not to have been
granted." Then it recites the facts I have been tell-
ing you as to the case of Piper, and prays that the
patent may be revoked. Particulars of objection
have been presented in accordance with the Act.
Mr. Justice North: If you have not the evidence,
all I can do is to order it to stand over until you have.
No one appears for the respondent.
Mr. Wallace: No, my Lord. We have an affidavit
of service. We wish to save these people as much
expense as possible, and, in fact, to save expense on
each side. Her only statement when she was served
with the petition was that she had used it for twenty
years. That, of course, would not be any ground.
We will file the affidavit, my Lord, in the same form
we have it here. Subject to filing the affidavit
verifying the petition, if your Lordship would grant
the revocation of the patent I think it would save
expense to both the Pharmaceutical Society and the
respondent. It is quite evident that the patent is not
one which it is wished to defend. On one occasion
before, my Lord, it was allowed to stand over to go
into the witness list, and it caused a great deal more
expense.

Mr. Justice North: I did not propose it should go
into the witness list.
Mr. Wallace: Subject to filing an affidavit verify-
ing the petition, will your Lordship allow the patent
to be revoked?
Mr. Justice North: Yes. But I think it must be
in the paper to be disposed of after the affidavit is
filed. You see the respondent does not appear. The
office copy affidavit ought to be produced now.
Mr. Wallace: We could get it done to-day, I
believe, and I could mention it again.
Mr. Justice North: It may be at the head of the
paper on Thursday, if you like, at the sitting of the
Court. Then the order may be made without any-
thing further being done, excepting your telling me
you have the affidavit.

On Thursday, August 9,
Mr. R. Wallace, in answer to his Lordship, said he
had now an affidavit verifying the statements in the
petition.
Mr. Justice North: Then the order may go, to be
dated to-day.

Dispensing Memoranda.

(Continued from Vol. XXI., p. 1047.)

[649] The following prescription was recently sent
to a pharmacy by a customer who complained that
she could not get it uniformly dispensed where she was
staying:—

B. Bismuthi carb. .................. 3l.
Tinct. calumb. .................. 3l.
Spirit. chlorof. ................. 3l.
Sod. biform. ................. gr. xl.
Mudii tragac. ................. 3l.
Ag. ad. .......................... 3l.

M. Sumat 3l. ter in die post ob. 1obis.

[650.] As illustrating how confusion may be caused
by inaccuracy in copying, the following French
prescription seems worthy of publication:—

Sulfate de quinine ............... 7 gr. 
Bi-Carbonate de Soude ......... 7 gr.
Poudre de Douver ............... 7 gr.
Mealez de divide. On prendre trois par jour avant
les repas.

Several words are misspelt, the word "grammes"
in two different ways. The figure "7," as written, is
in each case crossed by a horizontal line, as is com-
monly done in France and Germany.

Answers to Correspondents, etc.

B. Lucas.—1. Lysimachia vulgaria; 2. Erythraea
tecumtorum.

E. A. Burgess.—Kindly send popular name is
printed characters, as it is difficult to decipher in
writing. Can you also send a leaf of the plant?
"Triflorum."—It is Triflorum fragiferum.

Campbell, Hogg, Ingham, McDerment, Naylor, Thompson.
Blaud’s Pills.

BY JOSEPH INCE.

Dr. Blaud, the inventor of this preparation, was Head Physician at the Hopital de Beaune, Gard, and corresponding member of the French Academy of Medicine. The original formula was much heralded in contemporary journalism, and was specially recommended by Mérat et de Lons, as well as by M. Bouchardat.

According to Auguste Blaud, nephew and successor, the formula, which was not a secret remedy, was first given in 1831, and was inserted in the Nouveau Codex Francais, p. 555, formula 612, date 1866, and has since that time up to the present been prepared in exact accordance with the directions which are here translated.

Blaud’s Ferruginous Pills.

Salts of protocate of iron, purified, dried and powdered, thirty grammes…………….30
Carbont of potassium, pure, dried, thirty grammes…………………………………30
 Gum arabic in powder, five grammes………..5
 Water, thirty grammes…………………..30
 Simple syrup, fifteen grammes………….15

Dissolve the gum in a porcelain capsule, by the heat of a water-bath, in the quantity of water prescribed; add the syrup and the sulphate of iron; stir for some moments in order to render the mixture homogeneous; add the carbonate of potassium previously powdered, constantly stirring with an iron spoude, and continue heating until the mass has acquired a pilular consistence, rather more hard than soft. Withdraw from the source of heat and divide the mass into 120 pills, which must be dried in the stove (drying closet) and alvared. Put the pills into well-corked bottles: each pill weighs about 40 centigrammes.

The pills as so made have a very attractive appearance, the name Blaud being stamped on each. Judging by a sample forwarded by Auguste Blaud, February 16, 1892, the shape is permanently retained and the ferrous salt is in an unchanged condition.

A vigorous protest appeared in the Journal de Medicine de Paris (Nov. 15, 1891) against the idea that novelty is to supersede older and tried remedies, and it was pointed out that at least as regards ferruginous preparations we may be content to abide with those already sanctioned by authority and by experience.

The illustration drawn from the Codex formula of these “pillules ferrugineuses” was viewed with satisfaction by the pharmacy at Beaune.

Variations have been constantly attempted, with more or less success, in the manufacture of a pill that shall contain a non-oxidised carbonate of iron. The Phiala Ferrisi of the British Pharmacopoeia seems to leave nothing to desire; the mass is ready made, and the pills keep their shape. The formula is based upon the judicious use of glycerine, which is undoubtedly a desirable introduction. Other antecedent formulas have been constructed on a similar principle, and with equal advantage. It is just to the original inventor to state, that while these adaptations of the Codex form may be recommended as effective remedies, they do not yield a more permanent product than the original.

The Asafetida Plants.

BY E. M. HOLMES, F.R.S.,
Curator of the Museum of the Pharmaceutical Society of Great Britain.

Up to the present time several plants yielding a milky juice, having the odour of asafoetida, have been discovered in various countries, extending from Turkestan and Kashmir to the north-west of Persia; but, with the exception of Kempfer, who in 1687 observed its collection in the neighbourhood of Disguin, in the province of Laristan, of Beller, who witnessed the collection of an asafoetida in the neighbourhood of Candahar in 1887, and of myself, who, in my journey to the source of the Oxus, found it to be produced in the mountains around Saigon, no one has actually seen the drug collected, and in neither case has the plant yielding it been identified with absolute certainty. It seems, however, that it may be possible by a process of elimination to ascertain which of the plants do not yield the commercial article, and that thus the plants which actually do yield it may be determined.

Dr. J. E. T. Aitchison, C.I.E., F.R.S., who hopes to determine the source of several of the feld gums resinas concerning which much uncertainty still prevails, has just forwarded his first contribution towards that end. In a letter received from him, from Kashmir, he says that he has come upon Ferula Nowrak, Boiss., at the very locality, he believes, where Falconer originally found the plant in 1838, since which time no one has found it, so far as he is aware. This is the plant that has twice flowered at Edinburgh, and once at Kew, and is still in cultivation in various botanic gardens. It was noticed by Mr. W. R. Lawrence, F.C.S., C.I.E., on his official tour through Jammu and Kashmir in 1893, when it was in flower, between Astor and twenty miles north, near Doivan. Dr. Aitchison has obtained, through this gentleman, roots and stems with the remains of leaves and flowers, in very bad condition so far as botanical specimens go, but sufficient for the identification of the species. He states that “the people at Astor do not in any way collect the gum resin asafoetida, but people passing through Astor on the road from Kashmir to Gilgit collect the leaves and young flowering shoots and employ them in place of other vegetables. Those who use them are usually Hazaras or Afghans; they of course consider this to be the plant of their own country (F. foliata, Regel) from which the commercial product of their country is produced. As far as Laurence knows, and from all the information I have heretofore been able to collect, no asafoetida of any sort is collected anywhere in Kashmir territory, and any that may possibly pass through Kashmir to India must be collected somewhere in Afghanistan proper, and come into Kashmir via the western and northern routes.”

Dr. Aitchison has also been able to clear up another doubtful point. In the ‘Flora of British India’ (vol. 1, p. 705) Ferula foliata, Regel, is given as a synonym of Ferula Jasmscenae, Vatke. Some years ago (Pharm. Journ. [3], xix., p. 44) I pointed out that although the two plants are as like each other in foliage as are Ferula foliata and Dorema ammoniacum, yet that F. Jasmscenae, Vatke, at all events in the dried state, had not the slightest odour of asafoetida, and could not possibly be iden-
tical with *Ferula fatidissima*, Regel. Dr. Aitchison now writes that *Ferula Joesckiana* is plentiful all around Gulim (3600 feet) near Srinuggur, in Kashmir, and that "anyone who had ever seen the plant in a living state and examined its milky juice, would never for a moment consider that assafetida or any alliaceous gum resin could be obtained from it. The juice is strongly celery-scented and pleasant to a European's sense of odours, and in no way resembles that of the assafetida-producing *Ferulas*. From Joesckhe's oral description to me of the nauseous odour of one of his Umbelliferae I still expect someone to find an assafetida-producing *Ferula* in Lahul!"

It is therefore evident that although there may be a number of plants capable of yielding an assafetida, the drug is only collected in certain localities, and not from all the species capable of yielding it.

---

**PREPARING TEETH FOR MICROSCOPIC STUDY.**

**BY W. B. CHRISTENSEN, D.D.S.**

When the tooth has been extracted, it must immediately be brought into some conserving fluid—as alcohol or watery solution of bichloride of mercury—to prevent the pulp from shrinking. Also, in all further manipulations, as cutting, sawing, or grinding the sections, careful attention must be given that the tooth or section is at no moment without an excess of moisture. If teeth of rabbits or dogs are used, it must be remembered that the tissues of the pulp stick more to the wall of the pulp-chamber than in human teeth. This is important at the first opening of the tooth. If human teeth are taken from dead bodies, it must not be more than six hours after death.

In order to enable the preparing drugs to enter the pulp, it is necessary to open the tooth and partially expose the pulp in such a manner that the pulp is not hurt. For this purpose we make a section with a sharp, fine saw on both sides of the tooth about midway of the crown, and cut off the part with a pair of strong excising or splitting forceps. The end of the pulp will then be exposed without being hurt. At the apex of the root a short piece is cut off in a similar way. For fixation of the tissues, the tooth is placed in a saturated solution of bichloride of mercury in water for about eight to twelve hours, after which it is washed in running water for two hours.

To harden the tissues of the pulp, the tooth is then placed in alcohol of low degree, the strength of which must be gradually increased from 30 to 50 per cent., and from 50 to 70 per cent., leaving the tooth from eight to twelve hours in each of the three stages. From the bichloride of mercury there will be left a black precipitate on the specimens which can now be removed by placing them for about twelve hours in 90 per cent. alcohol, to which 14 to 2 per cent. tincture of iodine has been added. The iodine is removed by placing the specimens in pure alcohol until they recover their former white appearance. After the process of hardening in alcohol, the teeth can be cut in two or three sections by means of a fine, sharp scroll-saw. The next step is to stain the specimens. There are a great number of dyes used for staining preparations for microscopic studies. Dr. Weil, in the description of his method, mentions a great many, but he says he has obtained the best results with "aqueous borax-carmine," prepared in the following manner:—

Eight grammes of borax is powdered in a mortar together with 2 grammes of carmine, and then mixed with 130 grammes of ad. dest. After twenty-four hours the solution must be well filtered, and is then ready for use.

The sections, when taken from alcohol, are washed in running water for about fifteen minutes, and then transmitted to the dye for twelve to twenty hours, in which time they will become intensely coloured. The excess of dye is removed byplacing the sections in 70 per cent. alcohol, to which 1 gramme of hydrochloric acid has been added to each 100 C.cm. for as long as they have been in the dye. It is then well to place them in 90 per cent. alcohol for about twelve hours, and afterwards in oil of cloves for one or two hours. This last procedure makes the specimens more transparent.

We have now come to the treatment with Canada balsam. This must in the meantime have been prepared in the following manner: A quantity of Canada balsam, as obtained from the druggist, is placed in an evaporating dish, and kept over boiling water until the balsam, by cooling, becomes solid and brittle like glass. This takes from twenty to thirty hours, according to the quality of the balsam.

When the sections are taken from the oil, they must be cleaned with pure xylool, and then quickly immersed in chloroform, to remain twenty-four hours. Then, if sufficient of the hardened Canada balsam is added to the chloroform to give a weak solution, and after another twenty-four hours the solution must be saturated with Canada balsam; but the solution containing the specimens is then again put into an evaporating dish, and placed over hot water until the balsam once more becomes solid. As the chloroform boils at a low temperature (50–61° C.), the heat from the water must, to begin with, not be higher than about 60° C.; later it can be increased, but altogether slowness of the solidifying process is in favour of the results. Consequently, the procedure takes from twenty to thirty hours.

When the balsam, by cooling, becomes solid and brittle, the specimens can be cut out with a small, sharp chisel, and with a fine, sharp scroll-saw be cut into sections suitable for grinding. The grinding is done as when small sections of bone are ground for microscopic study, always under application of excess of water. The pressure must be very gentle, especially when the specimen gets thin; the result now depends somewhat upon the skillfulness of the operator. When the section is thin enough, which must be controlled under the microscope, it must be carefully cleaned in distilled water, and finally mounted in Canada balsam.

This whole procedure may at first seem rather complicated, but the results certainly repay the labour.—*The Dental Cosmos*, through *British Journal of Dental Science*. 
Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the Editor, 17, Bloomsbury Square, London, W.C.

Instructions from Members, Associates, and Students, respecting the transmission of the Journal, should be sent to Mr. Richard Beesbridge, Secretary, 17, Bloomsbury Square, London, W.C.

Advertisements and remittances must be sent to the Office of the PHARMACEUTICAL JOURNAL, 5, Serle Street, Lincoln's Inn, London, W.C., where Copies of the Journal may be purchased. Cheques and Money Orders should be made payable to "Street Brothers."

ORDO RERUM.

The calling of a pharmacist is not one that can be tied up by hard and fast rules. The exigencies of the work are such that he must in case of need and pressure depend on the local help of his employer of every rank—that of his fully qualified "Major" or pharmaceutical chemist, as well as of his errand boy. His hours of labour cannot be regulated by any eight or ten hours' bill. He must be at the beck of the public whenever pain, suffering, and disease make their urgent call. So that however much he may desire to enjoy a little well-earned leisure, the pharmacist can never feel certain that this will not be disturbed by the night bell. In establishments where relays of qualified assistants alternately work the early and late duties of attendance, the labour and strain of nervous tension is less irksome, if it be more intense while it lasts, so that—in those especially where both qualified assistants and juniors are employed—a certain amount of regularity can and must be maintained, as regards hours of labour and the details of the work to be done. Much, therefore, of both these conditions becomes a matter of routine. On the whole, the pharmacist's work possesses the charm of variety, but unless the daily routine of it becomes constituted into rules, written or unwritten, a pharmacy would lack that first law of heaven—order. To rule properly, therefore, in many cases means that these regulations must be compiled in a formal manner and used with the authority of the proprietor, in fact, that an ordo rerum must exist, as of old, embodying to ripe judgment of those who have gone before. We have found it necessary to commit their "wise men" to print, and we have no doubt the well-embossed card is to be found in many establishments at the present time. We have three such before the present time. In "The Rules, etc., compiled by a revered father in pharmacy, besides 'Rules for the House' we have others bearing on promptitude, attention, order, accuracy, safety, neatness, delivery, interference, and success in business. The delicate ethical relations between the prescriber and the pharmacist are carefully noted, and it is discretely directed how they are to be treated. Another ordo rerum gives a number of "Hints and Suggestions to Assistants" on dispensing, and it has printed in red ink on the face of it the following in regard to the "Sale of Poisons":—

"Assistants must have a perfect knowledge of the Poison Schedule of the Pharmacy Act, 1868, and they must carry out the regulations of that Act in every detail. A copy of the Schedule is displayed in the Pharmacy for reference, so that no plea of ignorance of its contents will be admitted."

The third appeared in the American Druggist, and has been re-published by a contemporary in this country. It is not adapted to English pharmacy, as it would destroy the good feeling between employer and employed which exists to a greater extent with us than appears to be the case across the Atlantic (a system of fines forms part of it, and the employés are to embrace every suitable opportunity to recommend our own specialties, and to sell as many of them as possible). The qualified assistant with us is now a responsible agent, one who must use his discretion and knowledge in the interests of the purchaser as well as of his employer. He must sell or not sell as his judgment directs, if he considers the purchaser is not a proper person to be entrusted with what he demands, be it morphine or opium, or a nostrum containing these in disguise.

In directing the ways of a pharmacy, especially in regard to the manner of conducting the sale of poisons, we are of opinion that much may be done by judicial rules, and by frequent attention being drawn to them. They will not, of course, replace the necessary personal admonition and supervision by the principal, any more than would the written prayers presented to Jove replace the invocation, if the god were merely addressed "Oh! Jupiter, these are my sentiments," and the supplicant then went to sleep. Still, rules, especially in regard to the sale of poisons, will help to maintain order in a well-regulated pharmacy. They will not, of course, exonerate the principal from the neglect of duty on the part of an employé in conducting a sale of poison, but they will tend to extenuate the offence. In framing rules the principal of a pharmacy must not be a martinet. Much is best unwritten, also the finely balanced relations of employer and employé are lost. But by carefully directing, in outline, how cases are to be treated as they arise, he will do much to help his employé to act when left to his own resources. Each establishment needs to draw up its own regulations, as no two are exactly alike in every respect.
THE MUSEUM TRADE.

A medical correspondent writes to point out, as complementing and corroborating the tenor of the article on this subject which appeared in our issue of July 28 (see p. 78), an article appearing in the British Medical Journal of the same date, under the heading, “The Spirit of Quackery within the Pale of the Profession,” by Dr. J. West Walker. In illustration of this he quotes the following passage —

“When I send to a consultant I invariably ask myself what novelty shall I have to procure, and this, notwithstanding it is the rule to have my surgery well supplied with most of the established therapeutic agents. The recently-born mineral water or proprietary dietetic, the endless variety of the carbon derivatives with their break-jaw names, the latest importation from America, some form of course of antiseptic, the newest tabloid, capsule, or cachet, some drug, it may be, not to be found in the Pharmacopoeia nor the usual trade lists, but only to be obtained from a particular chemist; these and such like form a tempting catalogue of choice novelties from which selection may be made according to fancy.”

We are glad to find that the inconvenience of the employment of the latest pharmaceutical novelties is felt not only by dispensing chemists, but also by medical practitioners.

UNVEILING A STATUE OF SYDENHAM.

An interesting ceremony took place at Oxford on Thursday, August 9, when the Chancellor of the University, the Marquis of Salisbury, K.G., attended at the University Museum for the purpose of accepting, on behalf of the University, a statue of Thomas Sydenham, presented by the Warden and two Fellows of All Souls’ College. Perhaps it was to the blame of their college that they had not before made this gift to the University of Oxford. But it had fallen now, he thought, on a happy time that they should be able to present it, because it formed the completion of the figures of these ancestors of medical science, which, like the old Romans, they placed in the entrance of that palace of science; and it came at a time when they were able to see how great had been the growth of the cultivation and renewal of the study of Nature of which this splendid Museum had been the out come and was the seed. Perhaps at an earlier time they should not have appreciated how much had been done in that respect, and perhaps they should not have felt as they felt now how thoroughly appropriate it was that the great masters and heroes of medical science should be conspicuous ornaments of that Museum. For the Museum marked the growth of the new study, and it had arisen chiefly by the efforts and under the authority of Sir Henry Acland, the great representative of medical science at that University, and in honouring Sydenham, as they did, they were honouring his great successor, to whom, more than to any other man, the renewal of the study of Nature in the University was due, and to whose efforts and to whose memory that splendid building and the more splendid incorporal construction in which it was built would be a lasting and brilliant testimony.

NEW CONSTITUENT OF THE ATMOSPHERE.

At the meeting of the chemistry section of the British Association on Monday last, the discovery of a new gas in the atmosphere was announced by Lord Rayleigh and Professor Ramsay. Whilst working upon the density of gases Lord Rayleigh found that the density of nitrogen obtained from the atmosphere was greater by about half per cent. than that of the same gas obtained from other sources. Professor Ramsay took up the investigation, and it was found that, on passing electric sparks through air and absorbing the resulting nitrous fumes, a residue remained, the spectrum of which differed from those of oxygen or nitrogen, having a single blue line much more intense than the corresponding line in the nitrogen spectrum. The gas may also be isolated by exposing atmospheric nitrogen to the action of magnesium. As the magnesium gradually absorbs the nitrogen, the density of the residue rises to nearly 30. Professor Emerson Reynolds suggested that if the new substance proved to be an element it would occupy a place in Mendeléeff’s table among the platinum metals. It appears probable, however, that it is simply an allotropic modification of nitrogen, which it resembles in its extreme inertness. The gas constitutes about 1 per cent. of the atmosphere, and about 100 C.C. of it has so far been isolated.
PHARMACEUTICAL EDUCATION.

In the Journal for September 16, 1893, particulars were published of classes and courses of laboratory instruction, suitable for pharmaceutical students, at various institutions throughout the country. The information then given having been found useful, it is proposed in an early issue of the Journal to bring into print and supplement it by other matter of special interest to students. It is requested, therefore, that divisional and local secretaries and secretaries of local pharmaceutical associations will assist the Editor by forwarding as early as possible detailed information of any suitable classes, etc., in their respective districts—in botany, chemistry, materia medica, pharmacy, and physics.

UNIVERSITY OF LONDON.

There now seems to be a better prospect of a satisfactory agreement being arrived at in connection with the proposed reconstitution of the University of London as a teaching as well as an examining body, for at the last meeting of the Senate of the University it was resolved as follows:

"That it is desirable to memorialise Government to take immediate steps for the appointment of a statutory commission to frame statutes in general accordance with the report of the Gresham Commission, but with power to make such modifications as may seem to them expedient after considering any representations made to them by the Senate, Convocation, or any other bodies affected."

UNIVERSITY DISTINCTIONS.

At the recent examinations of the Durham College of Science, R. R. Hallaway, a student of the Pharmaceutical Society and son of Mr. John Hallaway, local secretary for Carlisle, passed the first associateship examination and gained the T. Y. Hall scholarship, which is tenable for three years, and is worth, in the aggregate, about thirty-five pounds per annum. Another pharmaceutical student, Leonard G. Lennfrst, son of Mr. W. G. Lennfrst, a member of the Pharmaceutical Society, has passed the Intermediate Examination in Science of the University of London; and A. W. Sikes, B. Sc., an associate of the Society, has passed the Intermediate Examination (honours) in Medicine of the same university.

THE SALE OF CARBOLIC ACID.

According to the Sheffield Telegraph, on August 13, before commencing an inquiry at Bakewell, the coroner (Mr. Symonds Taylor) said he would like to refer to a matter which occurred at the last inquest. The jury in that case made a strong recommendation that carbolic acid ought to be scheduled as a poison, and he wrote to the Secretary of the Pharmaceutical Society, enclosing him the recommendation of the jury. The Secretary replied that the Council of the Society had three times officially resolved that carbolic acid ought to be scheduled so as to prevent its common sale, but so far the Privy Council had not thought it proper to give its approbation of the suggestion. The coroner added that he had since written to the secretary of the Privy Council, giving him the effect of the jury's recommendation, to which he had only received a formal acknowledgment.

FEDERATION OF LOCAL PHARMACEUTICAL ASSOCIATIONS.

A meeting of delegates appointed by the various pharmaceutical associations was held at the Randolph Hotel, Oxford, on Monday, July 30, 1894.

The following associations were represented:

The Cambridge Pharmaceutical Association, by A. S. Campkin.
Glasgow and West of Scotland Pharmaceutical Association, by W. L. Currie.
Liverpool Chemists' Association, by Dr. Symes.
London Chemists' Assistants' Association, by E. H. Gane.
Manchester Pharmaceutical Association, by H. Kemp.
Midland Pharmaceutical Association, by C. Thompson.
Nottingham and Notts Chemists' Association, by A. C. Bolton.

Apologies were received from J. F. Eardley, representing the Sheffield Pharmaceutical and Chemical Society; J. Harrison, Sunderland Pharmaceutical Association; J. F. Tocher, Peterhead and District Chemists' Association; and W. H. Gibson, Brighton Association of Pharmacy.

The chair was taken by Mr. W. Gowen Cocroft, Shrewsbury, Vice-President of the Pharmaceutical Society, who said he was pleased to give his countenance to a movement having for its object the closer union of pharmacists. He felt sure a federation such as the one now proposed would, under certain conditions which he enumerated, receive the approval of every pharmacist who had the welfare of pharmacy and the Pharmaceutical Society at heart. He then asked the hon. secretary to read the report of the interim committee appointed at Nottingham.

The report showed that a circular letter had been issued to the various associations throughout the country, asking them to appoint delegates to represent them. The replies received were most favourable; but some associations, owing to various causes, had not yet replied. It was a source of regret to the committee that many associations had apparently ceased to exist, as evidenced by the fact that many letters had been returned marked "not to be found."

The committee is of opinion that in every town where there are half a dozen pharmacists an effort should be made to cultivate a closer bond of union by the formation of an association which should be affiliated with the Federation. Only four associations have declined to appoint delegates.

A long and animated discussion took place, in which all the delegates took part. It was agreed that the main object of the Federation was to promote a greater unity. It would not undertake any legal work, as that was already provided for; but it would assist in anything that might arise, having for its object the better protection of trade interests. Finally, it was unanimously agreed that a committee be appointed, consisting of one delegate from each of the associations represented, with instructions to draft a code of rules to be presented at another meeting to be held at a central place a few months hence.

Mr. Harry Kemp, Manchester, was unanimously elected the first President; Mr. W. L. Currie, Glasgow, Vice-President; Mr. Chas. Thompson, Birmingham, Hon. Secretary and Treasurer.
Charcoal, as a base, is objectionable on account of its colour—it is liable to accumulate in the sulcus between the gum and the cementum, forming an unpleasant looking dark line.

We are compelled then, in choosing a base, to fall back upon our old friends, the chalks of the Pharmacopoeia. These fulfil as accurately as possible the required duty.

We really clean our teeth then just as we do our silver and plated goods; we have not yet found a better way. Indeed, to test the quality of our mechanical base we might do worse than to clean a new silver spoon with it, and then with the aid of a lens examine the surface of the silver to see whether it has been out. If it has suffered injury, let us by all means try to find a better base.

To follow out the plate-cleaning idea one might, after cleaning the fronts of the incisors, give them a final dry polish with wash-leather.

On comparing the claims of the official chalks, we much prefer the creta precipitata to the creta precipitata, for every particle of the former has been suspended in water by virtue of its own lightness, whereas every crystal of the creta precipitata has been thrown down from a condition of semi-suspension in a denser fluid by means of its own greater density. It may be contended that the precipitated form is not entirely exclusively crystalline, but it will be admitted that it is composed largely of crystals.

The mention of crystalline calcic carbonate makes us think of it in its native form, white marble, or who would think of cleaning a delicate structure such as a powder having physical properties in any degree like those of marble?

Having satisfied ourselves by means of the official test that our prepared chalk does not contain silt, we have a base as nearly perfect as possible.

The presence of myriads of germs in the saliva easily proved, and there is danger that lingering trace of either solid or liquid food may become, even in the healthy mouth, both septic in influence and acid in reaction.
We do well to counteract these tendencies by giving our base an increased antacidity, and also by making it astringent, for it is obviously necessary for the well-being of the dental tissues that the fluids of the mouth should be kept alkaline and aseptic.

A small proportion of such an antacid as bicarbonate of sodium gives the necessary extra alkalinity. Only a small proportion is required, because healthy saliva is itself alkaline, and our mechanical base is already slightly so.

For the astringent property we plead strongly for the use of oil of cinnamon. It is free from the objectionable qualities of the harsher astringents, such as carbolic acid or eucalyptus oil. Experiments prove it to be an efficient germ-killer. We do not think its astringent property unduly valued. Moreover, used in proper proportion, it is pleasant to the mouth, and imparts a most delightful sensation of cleanliness and sweetness.

Should the typical dentifrice contain an astringent? We think not. Most astringents are unpleasant, and unsuitable, if only for the sake of the children who will be expected to use it.

We leave the embellishing of the preparation entirely to the skill of the pharmacist. As to colour, we see no objection to whiteness. If this be unpopular, we see no objection. We care to use only harmless and neutral-looking ingredients.

We welcome the fashion of putting up the dentifrices in wide-mouthed bottles with sprinklers, and commend any method of putting up in which there is a temptation to dip the wet brush into the powder.

We advise putting the fullest directions on the label. These should include the rinsing of the mouth with water after using the powder, and advise as to the use of a soft brush. Warm water is indispensable in winter, especially for children. If the dentifrice be used once a day, bedtime is better than morning, and both are to be preferred.

Mr. GROVES (who had taken the chair during the temporary absence of the President), said the paper was a very useful one, but did not call for much comment or criticism. He did not agree with the statement that astringents should be avoided because they were unpleasant; the real question was the utility of the dentifrice; and in some cases the addition of an astringent would be decidedly advantageous.

Mr. MOSS asked if silica would be considered objectionable, provided it were in the form, as in some of the industrial earths, of very fine powder.

Mr. UPTON pointed out that there was nothing about tooth powder, but he denied the statement that precipitated chalk was thrown down from a condition of semi-suspension. When properly prepared it was made from two liquids in suspension, and it was only a question of drying these solutions to a very gentle dilution to get a chalk of about impalpable powder. It was prepared from two solutions—chloride of lime and carbonate of sodium; but there were all sorts of products passing under the name of precipitated chalk, which differed as much from one another as bread from brood-cloth.

Mr. MARSHALL suggested that unless a tooth powder contained something to take a grip of the teeth it would always fail in its purpose. Cinnamon had been added as a flavouring ingredient, but he thought it could have been omitted, when combined with other things, such as carbonate of soda, would soon lose its force.

Mr. TURNER, in reply, said he only objected to the use of an astringent as a normal ingredient, and he were many cases where it was required, and it should be supplied. If silica could be found such a fine state that it would not scratch, he saw no objection to its use. By a condition of semi-suspension he meant that at the moment of precipitation chalk was formed; it was suspended just for the moment, but began to fall. Immediate suspension is a distinction to prepared chalk, which was suspended long enough to be carried away by the water. A great deal of harm was done by "gripping" tooth-powders, especially those containing pumice-stone. Of course, if oil of cinnamon were used, the powders should be moderately moist, not dry.

The Conference then adjourned until 2 o'clock.

On resuming, the following paper was read:

**EXTRACT OF NUX VOMICA.**

BY E. W. LUCAS, F.G.S.

Expressions of opinion have been invited as to whether it would be desirable to replace the present extract of nux vomica by an equivalent of powdery extract in the next edition of the Pharmacopoeia. The idea is not a new one; many have advocated it as early as 1859. The loss of moisture on drying and the consequent diminution in strength have been a frequent theme of discussion, and in 1891 Conroy proposed the incorporation of syrupy glucose as a means of preventing loss. Unny and Moss were rather in favour of stiffening the present extract by the addition of starch extractive matter to be obtained by a percolation of the marc with very dilute alcohol. Now it is not an easy matter, except by the aid of an effective drying room or oven, to obtain extract of nux vomica so perfectly dry that it will powder, and even when powdered and diluted it is difficult to preserve in this state, owing to its very hygroscopic nature.

Glucose recommends itself as a preservative agent, owing to its insusceptibility to variations of temperature, but many people object to anything not contained in the original drug being introduced into the finished preparation. Besides, it would not tend to stiffen, but rather to thin an extract already too liquid. Moss and Unny's plan for the addition of extractive matter is, perhaps, the least objectionable, but it involves increased labour and cost.

We owe our present process for the manufacture of a standardised extract and tincture to the researches of Döntan and Shortland, who first introduced it; and it seemed to leave little to be desired. Experience however has shown that there are several drawbacks to the process which, in the opinion of the author, might be obviated. In the first place, the extract is inconveniently thin and soon increases in strength, owing to loss of water; secondly, no provision is made for the removal of the fatty oil, and thirdly, alcohol is used in such large quantities as to make the cost of production very great. This last particularly applies to the preparation of small quantities of the extract, when, even if the spirit is recovered in the usual way, the loss may vary between ten and thirty per cent.

The author ventures to suggest the following as offering a method for the economical preparation of nux vomica extract, which while being firm in consistency and free from oil, shall be little liable to loss by evaporation, owing to the presence of glycerin in the finished product. Briefly the process is as follows:

Take of—

Nux vomica in fine powder ...... 16 ounces.
Glycerin........................................ 1 ounce by weight.
Acetic acid .................................... 2 fluid ounces.
Chloroform water ......................... a sufficiency.

Mix the acid with two pints of the chloroform water, and macerate the nux vomica in the mixture in a closed vessel for four days. Transfer to a percolator,
and when the fluid ceases to pass, continue the percolation with chloroform water until one gallon has been collected. The percolate is then evaporated at a low temperature—the glycerin being added towards the end of the operation—to 4 ounces by weight, and 10 grains taken, and the alkaloids determined in the usual way. From the data obtained the extract is brought to the required standard of 15 per cent. of the mixed alkaloids of strychnine and brucine.

If the corresponding dry extract is required, the glycerin must be omitted, and the evaporation continued as far as possible on a water-bath, and the extract finally freed from water in a hot oven or drying chamber, the product being afterwards rapidly powdered, and mixed with sufficient inert vegetable powder—such as altheas or liquorices—to bring the final strength up to 15 per cent. The powder must then be stored in small vials, which should be hermetically sealed.

The President having remarked that the question of nux vomica was a perennial one,

Mr. Naylor said the tendency appeared to be towards the standardization of preparations. He did not see any particular advantage in the method now suggested, though he could not speak positively, nothing having tried it. He had been accustomed to use a spirittuous preparation of the extract, to dry it carefully, and then to make up the preparation with sugar of milk, and he found no difficulty in obtaining it in a condition of powder. He was disposed to think that a spirittuous preparation made in the ordinary way would contain more extractive than when dilute acetic acid was used as the solvent. The aim was a galenic preparation, not merely to get out an alkaloid in its crude condition, and he saw no reason for adopting this method unless it possessed very decided advantages. He was distinctly in favour of a powdered extract, because they knew from experience that a fluid extract which might be standardized to day might not be of the same strength in a week's time.

Mr. Moss concurred in the view that the present extract was much too thin for convenient use, but it would meet requirements if it were standaridised to 20 per cent., or nearly 15. At present, if the process from the pharmaceutical point of view, devised before the next edition of the United States Pharmacopoeia was a series of preparations called "Abstracts," which were made from these standardised extracts by the addition of sugar of milk, but after ten years experience they had been dropped. He hoped Mr. Lucas would follow the subject, for he should like to see a powdered process, from the pharmaceutical point of view, devised before the next edition of the United States Pharmacopoeia.

Mr. Lucas, in reply, said, one great advantage using acetic acid for extracting was that it was much cheaper than alcohol, of which a great deal would always last if you had to use a large quantity to exhaust the drug; operating on small quantities from 5 to 20 per cent. was lost, and probably even manufacterers lost a good deal. Methylated spirit of the old kind might be used in making these extracts because it was all driven off again; but if you were not operating on a large scale, it was hardly worth while, and the new-fashioned methylated spirit, of course, could not be used. By using water, a great deal more extractive was obtained; with a spirit the amount in the case of nux vomica was very small. Again, the water did not extract any of the oil, while by the Pharmacopoeia process nearly all oil was extracted, which made a very different extract when used for pills. He had operated three different kinds of nux vomica, and found one yielded a great deal of extractive matter, and ony a little. Most people who made it on a large scale would have difficulty in getting it solid; 15 per cent. was not at all too thick for the market in order to make it keep. In hot weather, if percolated with very dilute acetic acid it went well, but a little methylated chloroform preserved it. With regard to the powdered extract, he did not believe in it. As the President had said, the A.b. 138

THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS. [August 13, 1893]
had been rejected in the United States; but if you required to dry the extract, he thought powdered alkae would be better diluent than sugar of milk.

---

**Note on Strichnino Ignatia.**

By F. Ransom, F.C.S.

The seeds of *Strichnino ignatia*, Lindley, have long been known to contain the alkaloids which exist in nox vomicus, Palleter and Caventon, in 1819, having shown that strychnine and brucine were present. The drug has since been examined by various chemists, the results of whose investigations generally indicated that strychnine is present to a much larger extent than in nox vomicus. In 'Pharmacographia,' it is stated that strychnine exists to the extent of about 1.5 per cent of brucine and to 5 per cent. This statement appeared to receive confirmation from Harrington in 1888 (Proc. Amer. Pharm. Soc., 1886, p. 14), who examined three samples of the seed, finding on an average 1.196 per cent of strychnine and 1.413 of brucine. In each case the strychnine was largely in excess, but as the method employed to separate the alkaloids in two of the instances consisted in washing the strychnine from the cake with alcohol, the accuracy of the results may be questioned. In the following year, Cobleis ('Proc. Amer. Pharm. Soc.,' 1886) examined five samples of the U.S.P. abstract, which yielded total alkaloids varying from 3.88 to 4.74 per cent, of which 1.38 to 3.26 was indicated as strychnine by Schwagerier's alkalimetric method.

In order to compare the active constituents of Ignatia with those of nox vomicus, the following determinations of the seeds were conducted by the methods introduced and employed by Dunstan and Short in their investigations of nox vomicus and its preparations (Pharm. Journ., 3, xii, 1035). It was found desirable to use 10 grams of the finely powdered seed, which was first percolated in the cold in the inner tube of a Dunstan and Short extraction apparatus, with 80 C.c. of chloroform containing 25 per cent. of absolute alcohol. When the liquid ceased to drop, the tube containing the marc was inserted into the outer tube, to which was fitted an upright condenser. The flask containing the percolate was attached, and by the heat of a water-bath the extraction was continued until the residue from a few drops of the percolate evaporated to dryness and dissolved in dilute hydrochloric acid ceased to give a precipitate with Mayer's reagent. The alkaloids were then extracted from the chloroformic solution by precipitation with dilute sulphuric acid (5 per cent.), which was then rendered alkaline with ammonia, and the solution exhausted with chloroform. The chloroform, on evaporation, left the alkaloids in a practically pure brucine or strychnine condition.

An attempt was made to exhaust the powdered seed with ammoniated chloroform, but it was not found practicable to extract the whole of the alkaloids with this menstruum.

Three specimens of the seed were submitted to analysis, with the following results:

1. 2.22 per cent. strychnine and brucine.
2. 1.31 per cent. strychnine and brucine.
3. 3.01 per cent. strychnine and brucine.

The mixed alkaloids found by Dunstan and Short in the authentic specimens of nox vomicus varied from 2.4 to 3.9 per cent., the average being 3.29. As seen above, the percentage in but three specimens of Ignatia varied from 1.72 to 3.01, with an average of 1.96; it would therefore appear that in the seeds of Ignatia the variation of the total alkaloids is greater, and the average percentage less than in nux vomicus.

An analysis was also made of an alcoholic extract of Ignatia by the official process for the determination of extract of nux vomicus. It was found to contain 16.7 per cent. of moisture and 9.6 per cent. of total alkaloids. The lowest found by Dunstan and Short in their analyses of twelve trade samples of unstandardised extract of nox vomicus was 10.38 per cent.

Attention was then directed to the separation of the strychnine from the brucine in the alkaloidal residues obtained from Ignatia. The ferrocynide method of Dunstan and Short ('Year-Book of Pharmacy,' 1888, p. 469) was employed, and the following results were obtained:

<table>
<thead>
<tr>
<th>Gram.</th>
<th>Percentage of strychnine by difference.</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1.285</td>
</tr>
<tr>
<td>b</td>
<td>1.65</td>
</tr>
<tr>
<td>c</td>
<td>1.405</td>
</tr>
</tbody>
</table>

The alkaloidal residue (a) was obtained from the extract. The latter two were derived directly from the seed, and indicated percentages of 8.4 and 1.45 of strychnine, and 88 and 1.36 of brucine in the crude drug.

The average proportion of strychnine in the alkaloidal residues obtained by Dunstan and Short from the twelve commercial samples of extract of nox vomicus was about 45 per cent., the highest being 50.1, and the lowest 31.3.

It appears, therefore, that although Ignatia may contain a larger proportion of strychnine compared with the brucine than nox vomicus, the percentage is more variable and the average percentage of total alkaloids, so far as may be judged by the examination of three specimens, is considerably less.

The glucoside, loganin, discovered by Dunstan and Short in nox vomicus and its preparations (Pharm. Journ., 3, xiv, 1025), appears also to be present in Ignatia. The extract was boiled with ether and the ethereal solution separated and evaporated to dryness. The residue, when warmed with concentrated sulphuric acid, gave a dark purple coloration characteristic of the glucoside.

The results here recorded would indicate that nox vomicus is the better adapted for pharmaceutical preparations, and that Ignatia, except for the occasional extraction of strychnine, is not likely to prove of much value for medicinal purposes, while the supply of nox vomicus remains abundant.

Mr. Umney said he was sorry he could not add anything to the information contained in the paper; but Ignatia was so scarce a drug that it was rarely met with in commerce, and was very little used, and he thought the superabundance of nox vomicus would prevent Ignatia being used in medicine. It was used on the Continent, but only to a small extent.

Mr. Holmes said he had had no experience in the extraction of the alkaloid. All he could say was that the seeds varied very much, at least in size, and very likely also in the amount of alkaloid they contained, especially if the smaller seeds came from unripe fruit.

The President said the Conference was much indebted to Mr. Ransom for preparing this paper in addition to his other labours as hon. sec. He had so little experience of Ignatia himself that he could say nothing about it.

---

**Remarks on Gnetum.**

By W. Elborne, B.A. Cantab., Demonstrator on Materia Medica and Pharmacy, University College, London.

Gnetum, L., is a genus of Gymnospermae, giving its name to the natural order Gnetaceae; the various species are trees or climbing shrubs, natives of the tropical forests of Asia and America, their stem,
yielding textile fibres more tenacious than hemp, while the leaves and seeds of certain species are said to be edible when boiled. My apology for drawing your attention to this subject is the remarkable ringed structure characteristic of the natural order Menispermaceae, and consequently not unlike "Pareira brava"—as a casual glance at the stem of *Gnetum scandens* will show.

The structure of the wood of Menispermaceae differs from that of other dicotyledons in that the vascular bundles of a young branch (which in most dicotyledons unite and form concentric rings of wood and liber) generally remain distinct in Menispermaceae, and are separated by broad radial masses of cellular tissue corresponding to the medullary rays of ordinary wood. After some time these original wood fascicles cease growing, and in the cortical cellular tissue exterior to the liber originates a second circle of bundles, similar to the first formed, excepting in the absence of spiral vessels. After these bundles have attained full development, they in turn cease to grow and form third circular forms in the cellular tissue of the bark, and so on.

Dr Barry* alludes to this anomalous mode of thickening of stems and roots in dicotyledons and gymnosperms as follows:—"As is the case with almost all anatomical peculiarities, the anomalies of secondary thickening also are in part evident phenomena of adaptation, and may in part even be explained directly as the outcome of mechanical causes; they are in part unexplained anatomical characters, which may be regarded as inherited. To the first category belong the anomalies of twining and climbing liane-stems from the most different families, whose non-climbing congeners have normal growth, as in the Bignoniaceae, Sapindaceae, Leguminosae, Malpighiaceae, and others to be named below. The lames from certain families, especially the Sapindaceae, or at least the majority of them, show very special peculiarities. On the other hand, a remarkable uniformity is often seen between those belonging to the most different families, as e.g., Menispermum and Gnetum, Bignonie, and some Apocynaceae."

Another point of interest in reference to the subject which I do not remember having observed in the trees of the *Abuta* and "Abutorum," popular Brazilian terms for Pareira brava (*Chondrodendron*, Ruiz et Pavon) and *Abuta*, Aubl., likewise an allied genus (Menispermaceae), yet the genus *Abuta*, Lou., is synonymous with *Gnetum*, L.

The following description is from Brandis‡—

* *Gnetum scandens*, Roxb., *Pl. Ind.*, iii, 519, syn. *G. obtusa*, Blume; *G. umbil.,* Ktmb.; *G. umbil.,* Bombay, is a stout climbing shrub, with opposite coriaceous elliptic-oblong petiolar leaves, 5 to 6 inches long, which turn black on drying; flowers monocious in cylindrical verticillate, paniculate spikes, with numerous short annular sheaths, the flowers mixed with articulate hairs closely packed in their axile. Male flowers monandrous, anthers of two distinct cells, opening by a slit at the apex at the end of a thick column, protruding from a thick clavate angular sheath, which splits in two. Female flowers consisting of numerous naked ovoids similarly arranged and mixed with articulate bracts. Fruit an oblong one-seeded drupe 1 to 1½ inches long, narrowed into a thick short stalk, red when ripe. The seeds are eaten. Common in the dense forests of the Western Ghat or the Konkan—East Bengal, Burma, Indian Archipelago, China. The wood of *Gnetum* consists of a large number of distinct wedge-shaped ligneous masses, which are arranged in concentric circles, and separated by cellular tissue. It thus resembles the wood of the Macaronesian *Gneta*.

Specimens of stems of *Gnetum scandens* et *G. urceus, from the Botanical Museum, Cambridge, were shown at the meeting.

Mr. Holmes said Mr. Elborne had kindly allowed him to see these specimens, and there was certainly a similarity between menispermaceous stems and *Gnetum*, which was very remarkable, and such as hardly expected to see. He had never met with any of these stems in commerce, but it was possible they might occur from time to time, and be a case of difficulty to the pharmacist. Hardly anything was known of the properties of the genus *Gnetum*, but a allied genus, the *Ephedra*, possessed myrrhaceous properties. It was desirable that the *Gnetum* should be further examined in case it came into commerce in future. He would ask Mr. Elborne if he could point out any special means of distinguishing the wood from pareira.

Mr. Moss said he many years ago made an examination of pareira root and stem as it came into commerce, and found about three times as much stem as root came to the London drug market, and was regarded as root. He made a microscopic examination of the stem and the root, and a description of them would be found in the *Pharm. Journ.*, [3], vi, 702, with diagrams. It seemed to him that the stem now shown was somewhat larger than the usual *Chondrodendron* stem, and also that the cortical portion was much more largely developed; it also had a brown tinct, though that was not much of a distinction between one stem and another. The fibre-vascular bundles seemed much more largely developed, but he did not know whether that would turn out as a closer examination. He should like to know if Mr. Elborne had made a pharmaceutical examination of the root at all. He had made some extracts of pareira stem with a view of ascertaining whether it was of equal value with the root for medicinal purposes, but did not complete the investigation. He believed he had some of the extract still and should be pleased to hand them over to anyone who cared to pursue the subject.

Mr. Reynolds said he could not contribute anything to this subject, which he ventured to say was a novel one to everyone present. He would, however, mention, for the benefit of investigators of rare unknown vegetable products from abroad, that the formation of the Imperial Institute afforded a means of obtaining information with regard to such products. He knew from experience in connection with the Yorkshire College of Science that some of the professors were now engaged on products derived from the Institute, and that Sir F. Abel was always ready to render investigators every assistance in his power. Mr. Elborne had driven it home to them when they were comparing *Gnetum* with the Menispermaceae that it was not unusual to find menispermaceous stems very similar to the typical structure of the stems of *Pinus*, and he was not surprised to find the general superficial physical characteristics in the case of the *Pinus*.

The President said they were very glad to have contributed to their proceedings from a member of the sister university. He must say that the word *gnetum* did not convey any idea to him, or he might have brought to the meeting a collection of stems and roots which he had shown which Mr. Deane used to puzzle some of his students at Bloomsbury Square, amongst which were specimens of *Chondrodendron*.

Mr. Elborne said he had not made any pharmaceutical examination in this subject which he simply intuited.
duced it as an endeavour to explain the botanical source of some of the numerous false pareiraes. With regard to distinguishing these from menispermous stems, there was a practical test, and that was that on the periphery of such roots would be found numerous fibres; in fact, fibre was obtained by the natives from various stems of Gnetum, which was said to be stronger than hemp, and the presence of these fibres would be sufficient to indicate the character. Mr. Moss alluded to the bark being more developed than was usual in the case of the botanical source, in a rather unusual way, by observing the absorption spectrum given by the various tinctures, but had not been able to develop the results into a paper for this meeting. He might refer to *Cocculus indicus*, which belonged to the same natural order, and afforded a very precious preparation, and was not unlikely to be confounded with some of the false pareiraes stems.

Mr. Alock remarked that the stem, which he had only seen since Mr. Elborne began his reply, seemed somewhat resinous. Would not that afford a distinguishing characteristic, seeing that the Coniferae to which the stem was closely allied were very resinous, whereas the Menispermous would probably not be so resinous?

Mr. Elborne said the section of one specimen was resinous, but he should not be inclined to attach much importance to that. He did not think Gnetum was a resin-producing plant as in all the same sense as the Coniferae. It was probably an accidental feature in that particular case.

THE RECOVERY OF RESIDUAL TINCTURES FROM MARCS.

BY R. H. PARKER, F.C.S.

The best method for recovering the residual tinctures contained in a marc will depend chiefly upon the quantity under operation and the kind of apparatus available. I propose to consider the question as it stands, preparing from 1 to 4 pints of tinctures, etc., with such apparatus as may be found in any pharmacy.

Two methods are available for the purpose in view:—Pressure and displacement by water; distillation being applicable to larger operations only.

1. Pressure.—This process is simple and expeditious, because the netting of the ordinary tincture-press leaves much to be desired. Though a tube, a considerable portion of which is filled with a porous solid, evidently admits of the fluid to permeate the tissues. The effect of pressure, too, is often strongly marked, and the speed is such that the rate of permeation shall be so rapid that the fluid shall pass between the particles at a greater speed than it can permeate through their tissues.

Displacement may be aptly contemplated by imagining two superposed fluids passing steadily through a porous tube, one above the other, the upper fluid being in contact with a porous solid; evidently admixture of the fluids will tend to increase with the speed of the process, while diffusion and especially admixture due to currents induced by varying temperatures will be less in the presence of the marc than in its absence.

"Downward" displacement by water.—Two parallel experiments were conducted; in each case 2 ozs. of cinchona flav. (in No. 40 powder) and 10 ozs. proof spirit were mixed in a 12 oz. bottle and occasionally agitated during three or four days, then poured into a glass tube percolator (2 feet long, 1 inch wide) having muslin tied over the lower end and resting in a funnel and bottle receiver; as soon as the marc filled the tube, and without allowing the liquid to drain away, the upper end was closed with a
perforated cork carrying a tube connected with a water supply.

In one experiment the water was forced in at the top, and the displaced tincture collected in fractions at the bottom.

In the other experiment the water was forced in at the bottom, and the displaced tincture collected in fractions at the top.

A comparative examination of the specific gravities of the fractions will necessarily reveal the slightest admixture of water in any portion of the product.

The sketch illustrates the two experiments.

Apparatus arranged for "downward" and "upward" displacement respectively.—(a) Glass tube filled with marc; (b) Pressure water supply; (c) Bottle to collect displaced tincture.

The following table indicates the specific gravities

The tinctures as far as No. 4 were bulked as "Tincture" (No. 5 might have been included, but over 40 czs. had already been collected); the gradually thinned off into the alcohol without any sharp line of division. The second series of percolates (B) was entirely alcoholic; the water following it would not pass through the muslin. The entire volume of spirit used was recovered without loss. The juncture surface between tincture and alcohol was not visible in the marc, but a distinct brown line encircling the percolator always evidenced the position and progress of the water through it. Comparing the mixed tincture percolates (A) with the mixed alcoholic percolates (B), the former had about 5 times the colour and about 12 times the pungency of the latter.

Linum Belladonna.

32 ozs. of powdered belladonna root, stirred with 48 ozs. rectified spirit until exhausted, allowed to percolate, then displaced with another 48 ozs. rectified spirit, which in turn was followed by water, and the percolate collected in fractions as before.

It will be seen from this table that a uniform liniment percolated as far as fraction No. 4, when it gradually thinned off into the alcohol down to fraction...
No. 9. No water appeared in the percolate until after No. 15, by which time 95 ozs. had been collected out of 80 ozs. taken at commencement. A black line round the morc always indicated the exact position of the water, and its first appearance in the percolate was

This was readily observed by watching the transparency of the falling drops. The last drop of No. 15 was limpid and spirituous; the first drop of No. 16 was like black treacle.

VI. Proof Spirit displaced by Water. — In preparing 4 pints of tinct. cinchona co. the saffron was used in its ordinary condition, the orange peel replaced by an equivalent of tinct. aurant.; the bark, serpentine, and cacholol in No. 40 powder; the whole of the menstruum added, and frequently agitated in a stopped bottle for six days; transferred to a percolator, the tincture re-percolated until bright, then followed by water and the percolate collected in fractions.

Tincture, 782 ozs., all bright.

cloudy, much lighter, some op. — very light, scarcely ppt. — very light, clear, coppery, ppt. — clear, a-colour of tinct. aurant., no ppt.

In this case the tincture percolate was uniform all but 1½ oz. (out of 50 ozs.) had been collected. The position of the water was scarcely visible in the morc, but its appearance in the percolate was clearly visible on placing the fractions side by side. The change of gravity could easily be detected by pouring small quantity of one fraction into a previous one, and between the eye and a strong light.

Tincture, 74 ozs.

18, clear, limpid.

14, cloudy, syrupy.

This experiment was unsatisfactory, the displacement being slow so that the watery contents of the percolator required occasional stirring in order to facilitate the process; this perhaps accounts somewhat for the comparatively large deficiency (6 ozs. on 80 ozs.). The tincture, however, was faultless.

**Tinct. Chirata.**

The ingredients for 32 ozs. of tinct. chirata were macerated for four days, then percolated in a cylindrical chimney glass, the lower end of which was tied over with muslin; the fractions of percolate had the following characters:

<table>

slightly opalescent.

rather darker than tinct., bright, slight sediment.

same colour as tincture, still very bitter.

The specific gravities of the fractions indicate clearly where to draw the line for tincture, but at a glance they all seemed alike from 0 to 13; however, on close comparative examination, the opalescent appearance of No. 6 raised suspicion, which was confirmed by the darker colour of subsequent fractions, while the specific gravity bottle finally removed all doubt. The continued bitterness in the marc after No. 13, clearly indicates that the B. P. formula by no means exhausts the herb.

**Tinct. Opii.**

The marc from four pints tinct. opii after percolation was displaced by water with the following results:

same colour as tincture, still very bitter.
The British Association for the Advancement of Science.

MEETING AT OXFORD.

The sixty-third annual meeting of the above Association commenced at Oxford on Wednesday, August 8, under the presidency of the Marquis of Salisbury, K.G., D.C.L., F.R.S., Chancellor of the University of Oxford, who gave the following address:

THE PRESIDENT'S ADDRESS.

My functions are of a more complicated character than usually is assigned to the occupant of this chair. As Chancellor of the University it is my duty to tender to the British Association a hearty welcome, which it is my duty as President of the Association to accept. As President of the Association I convey most unworthily, the voice of English science, as many worthy and illustrious presidents have done before me; but in representing the University I represent far more fittingly the learners who are longing to hear the lessons which the first teachers of English science have occasion to teach to visitors to this place.

In the account of the services the Association contains we can transmute a layman into any more precious kind of metal. Yet it is my hard destiny to have to address scientific matters probably the most capable and scientific audience in the world. If a country gentleman, who was also a colonel of a regiment of infantry, were any member of the body of the Commandant-In-Chief to be appointed to review an army corps at Aldershot, all military men would doubtless feel deep compassion for his inevitable fate. I beseech some spark of that divine emotion when I am attempting to discharge under similar conditions a scented, hopeless duty. At least, however, I have consolation of feeling that I am free from some of the anxieties which have fallen to those who preceded me as presidents in this city. The relations of the Association and the University are those of the entire sympathy and good will, as becomes common workers in the sacred cause of enlightenment and knowledge. But we must admit that it was always so. A curious record of a very different state of feeling came to light last year in the interesting autobiography of Dr. Pusey, which is the posthumous work of Canon Liddon. In it is related the first visit of the Association to Oxford in 1832. Mr. Keble, at that time a leader of University thought, writes indignantly to his friend to complain that the honorary degree of D.C.L. had been bestowed upon some of the most distinguished members of the Association: 'The Oxford Doctors,' he says, 'have truckled sadly to the spirit of the times in regard to the hodge-podge philosophers as they did.' It is amusing, at a distance of time, to note the names of the hodge-podge of philosophers whose academical distinctions so sorely vexed Mr. Keble's gentle spirit. They were Brown, Brewster, Faraday, and Dalton. When I recollect the lovable and serene character of Keble, I marvel that he did not probably the man in the University who had greatest power over other men's minds, to measure the distance we have traversed since then; and the rapidity with which the converging paths of these two intellectual luminaries, University and the Association, have approximated each other. This sally of Mr. Keble's was no past
address, is to remind you of the salient points in the annals of science since last the Association visited the town in which he is speaking. Most of them have been able to lay before you in all its interesting detail the history of the profession. To one of these was the eminent representative. If I were to make any such attempt I should only be telling you with very inadequate knowledge a story which is from time to time told you, as well as it can be told, by men who are competent to deal with it. It will be more capable to my capacity to make the enumerations I have to make to a survey not of our science but of our ignorance. We live in a small bright oasis of knowledge surrounded on all sides by a vast unexplored region of impenetrable mystery. From age to age the strenuous labour of successive generations wins a small strip from the desert and pushes forward the boundary of knowledge. Of such triumphs we are justly proud. It is a less attractive task—but yet it has its fascination as well as its uses—to turn our eyes to the undiscovered country which still remains to be won, to some of the stupendous problems of the natural study which, if we do not give them up, we shall, instead, therefore, of recounting to you what has been done, or trying to forecast the discoveries of the future, I would rather draw your attention to the condition in which we stand towards three or four of the most important physical questions which it has been the effort of the last century to solve.

The revolt against Aristotle is now something of the past. But the mental sciences which were supposed to rest upon his writings have retained some of their ascendancy even till this day, and have only slowly and jealously admitted the rivalry of the growing sciences of observation. The subject is interesting to us, as this undecisive state of feeling coloured the experiences of this Association at its last Oxford visit, nearly a quarter of a century later, in 1860. The warmth of the encounters which then took place have left a vivid impression on the minds of those who are old enough to have witnessed them. That much energy was on that occasion converted into heat may, I think, be inferred from the mutual distance which the two bodies have since maintained. Whereas the visit of 1832 was succeeded by another visit in fifteen years, and the visit of 1847 was succeeded by another visit in thirty years, the year 1860 was followed by a long and dreary interval of separation, which has only now, after a great many years, been terminated. It has enabled the lapse of time to affect the opinions of the large number of persons whose interest was excited by the more animated discussion of the animated discussion of the more animated discussion of the more animated discussion of the three or four of the most important physical questions which it has been the effort of the last century to solve. Some of them are like other chemists that any chemist can tell them apart: others differ immeasurably from each other in every conceivable particular. In cohesion, in weight, in conductivity, in magnetic properties in every degree. They seem to have as much relation to each other as the pebbles on a sea beach, or the contents of an ancient lumber room. Whether you believe that Creation was the work of design or of unconscious law, it is equally difficult to imagine how this random collection of dissimilar materials came together. Many have been the attempts to solve this enigma; but up till now they have left it more impenetrable than before. A conviction that here was something to discover lay beneath the persistent belief in the possibility of the transformation of other materials into gold, which brought the alchemists of the Middle Ages into being. When the immortal discovery of Dalton established that the atoms of each of these elements have a special weight of their own, and that consequently they combine in fixed ponderable proportions from which they never depart, it renewed the hope that some common on the elements might be found. This has been advanced that all these weights were multiples of the weight of hydrogen—other words, that each elementary atom was only a greater or a smaller number of hydrogen atoms compacted by some strange machinery into one. The most elaborate analyses, conducted by chemists of the highest eminence—conspicuously by the illustrious Stegun—were directed to the question whether there was any trace in fact of the theoretic idea that the atoms of each element...
consist of so many atoms, or even of so many half-atoms of hydrogen. But the reply of the laboratories has always been clear and certain—that there is not in the facts the faintest foundation for such a theory. That we have discovered spectral analysis and men thought that an instrument of such inconceivable delicacy we should at last find out something as to the nature of the atom. The result has been wholly disappointing. Spectral analysis in the hands of Dr. Huggins and Mr. Lockyer and others, as thought of, word the thought of, a little expected to be told. We have been enabled to measure the speed with which clouds of blazing hydrogen course across the surface of the sun: we have learnt the pace—the fabulous pace—at which the most familiar stars have been for ages approaching to or receding from our planet, without apparently affecting the proportions of the patterns which, as far as historical record goes back, they have always delineated on the evening sky. We have received some information about the elementary atoms themselves. We have learnt that each sort of atom when heated strikes upon the ether a vibration, or set of vibrations, whose law is its own; and that no one and the same combination of atoms in producing its own spectrum encroaches even to the extent of a single line upon the spectrum that is peculiar to its neighbour. We have learnt that the elements which exist in the stars, and especially in the sun, are mainly those with which we are familiar upon earth. There are a few lines in excess to which we can give no terrestrial name; and there are some still more puzzling gaps in our list. It is a great aggravation of the mystery which besets the question of the elements, that among the lines which are absent from the spectrum of the sun, those of nitrogen and oxygen stand first. Oxygen constitutes the largest portion of the air of our planet as well as our atmosphere, so far as we know it; and nitrogen is very far the predominant constituent of our atmosphere. If the earth is a detached bit whirled off the mass of the sun, as cosmogonists love to tell us, how comes it that in leaving the sun we cleaned him out so completely of his nitrogen and oxygen that not a trace of these gases remains behind to be discovered even by the sensitive vision of the spectroscope?

All these things the discovery of spectrum analysis has added to our knowledge; but it has left us as ignorant as ever as to the nature of the capricious differences which separate those elements from each other, or the cause to which those differences are due.

In the last few years the same enigma has been approached from another point of view by Professor Mendeleeff. The periodic law which he has discovered reflects on him all the honour that can be earned by ingenuity, laborious, and successful research. He has shown that this perplexing list of elements can be divided into families of about seven, speaking very roughly: that those families all resemble each other in this, that as to weight, volume, heat, and laws of combination, the members of each family are ranked among themselves in accordance to the same rule. Each family differs from the others; but each internally is constructed upon the same plan. It was a strange discovery—strangest of all in its manifest defects. For in the plan of his families there were blanks left, places not filled up because the properly constituted elements required according to his theory had not been found. For this Mendeleeff seemed a weakness in the Professor's idea, and gave an arbitrary aspect to his scheme. But the weakness was turned into strength when, to the astonishment of the scientific world, three of the elements which were missing made their appearance in answer to his call. He had described beforehand the qualities they ought to have; and gallium, germanium, and scandium, when they were discovered shortly after the publication of his theory, were found to be duly clothed with the qualities he required in each. This remarkable confirmation has left Mendeleeff's periodic law in an unassailably position. But it has rather thickened the cloud of mystery over the species of the atomic world. The discovery of these co-ordinate families points to some identical origin, without suggesting the method of their genesis, or the nature of the common parentage. If they were organic beings our difficulties would be solved by mattering in connexion with their development words from time to time vouchsafed to humanity which have the gift of alleviating so many perplexities and masking so many gaps in our knowledge. But the families of elementary atoms do not bred, as we cannot, therefore, ascribe their ordered differences to accidental variations perpetuated by hereditas and the influence of natural selection. The rarity of line and the abundance of its sister chlorine, cannot be attributed to the survival of the fittest in the struggle for existence. We cannot account for the minor difference which persistently distinguishes nickel from cobalt, by ascribing it to the recent inheritance by one of these metals of an advantageous variation from the parent stock.

The upshot is that all these successive triumphs of research, Dalton's, Kirchhoff's, Mendeleeff's, as they have added to our store of knowledge, have gone but little way to solve the problem which is elementary atoms have for centuries presented to our kind. What the atom of each element is, whether it is a movement, or a thing, or a vortex, or a point, or has inertia, whether there is any limit to its divisibility, and, if so, how that limit is imposed, whether the list of elements is final, or whether any of them be common origin, all these questions remain to be answered by a science as profound as the theory, which lured the alchemists to their tedious labor, and which may be said to have called chemistry into being, has assuredly not been realised, but it has not yet been refuted. The boundary of our knowledge in this direction remains where it was many centuries ago. The word discovery to which I should like to find unsolved riddles which have hitherto defied the scrutiny of science, would be the question of what is called the ether. The ether occupies a highly anomalous position in the world of science. It is often described as a half-discovered entity. I dare say that the ether is an eye that has not been opened for it would be a great exaggeration of our knowledge if I were to speak of it as a body, or even as a substance. When nearly a century ago Young and Fresnel discovered that the motions of an incandescent particle were conveyed to our eyes by undulation, followed by the motion of the eye and the particles they must have something to undulate. In order to find something, the notion of the ether was conceive and for more than two generations the main, if the only, function of the word ether has been to run a nominative case to the verb "undulate." Let our conceptions of this entity have a new extension. One of the most brilliant of the essays which Professor Maxwell has rendered to science been the discovery that the figure which expressed velocity of light, also expressed the multiplier required to change the measure of static or passive electric into that of dynamic or active electricity. The measurement that stretches out is electric light and the electric impulse move approximately at the same rate through space, it is probable that undulations which convey them are undulations of same medium. And as induced electricity penetrates through everything, or nearly everything, it follows that the ether through which its undulations are propagated must pervade all space, whether empty or whether occupied by opaque matter or transpar
which are at present inferred from it can be taken as conclusive. Infinitesimal bodies found upon the roots of plants have the proud office of capturing and taming for us the free molecules of the air, which, if we are to live at all, we must consume and assimilate, and yet which, without the help of our microscopic ally, we could not draw for any useful purpose from the ocean of nitrogen in which we live. Microscopic bodies are convicted of causing many of the most distressing diseases of the body, and the guilt of many more will probably be brought home to them in due time; and they exercise a scarcely less sinister or less potent influence on our race by the plagues with which they destroy some of the most valuable fruits of husbandry, such as the potato, the mulberry, and the vine. Almost all their power resides in the capacity of propagating their kind with infinite rapidity, and up to this time science has been more skilful in describing their ravages than in devising means to hinder them. It would be ungrateful not to mention two brilliant exceptions to this criticism. The antiseptic surgery which we owe chiefly to List, and the problem as it arose many millions years ago. Yet certainly the most conspicuous event in the scientific annals of the last half-century has been the publication of Mr. Darwin’s work on the ‘Origin of Species,’ which appeared in 1859. In some respects, in the depth of the impression which it made on scientific thought, and even on the general opinion of the world, its momentous effect can hardly be overstated. But at this distance of time it is possible to see that some of its success has been due to adventitious circumstances. It has had the chance of enlisting among its champions some of the most powerful men of the day, and it was a great fortune of appearing at a moment when it furnished an armory of weapons to men who were not scientific, for use in the bitter, but transitory, polemics of the day. But far the largest part of its accidental advantages was to be found in the remarkable character and propagation of its author. The quality of judgment, the simple-minded love of truth and the patient devotion to the pursuit of it through years of toil and of other conditions the most unpropitious—these things endeared to numbers of men everything that came from Charles Darwin apart from its scientific merit or literary charm. And whatever may be ascribed to his doctrine, nothing can ever detach from the lustre shed upon it by the wealth of his knowledge and the infinite ingenuity of his resource. The intrinsic power of his theory is shown at least in this one respect, that in the depart- ment of knowledge with which it is concerned, it has treated an entirely novel field of thought and has involved an entirely new method of research. Before his time the study of living nature had a tendency to be merely statistical; since his time it has become predominantly historical. The consideration how any organic body came to be what it is occupies a far larger area in any inquiry now than it did formerly. The actual question was not predominant—it may almost be said to have been ignored—in the Botanical and Zoological study of sixty years ago.
Another lasting and unquestioned effect has resulted from Darwin’s work. He has, as a matter of fact, disposed of the doctrine of the immutability of species. It has been mainly associated in recent days with the honoured name of Agassiz, but with him has disappeared the last defender of it who could claim the attention of the world. Few now are found to doubt that animals separated by differences far exceeding those that distinguish what we know as species have yet descended from common ancestors. But there is much less agreement in the case of plants, of which this common descent can be assumed, or the process by which it has come about. Darwin himself believed that all animals were descended from “at most four or five progenitors”—adding that “there was grandeur in the view that life had been originally breathed by the Creator into a few forms or one.”

Some of his more devoted followers, like Professor Haeeckel, were prepared to go a step farther and to contemplate a crystal as the probable ancestor of the whole fauna and flora of this planet.

To this extent the Darwinian theory has not affected the minds of the botanists or zoologists a great deal, and at least there is no unanimity in the acceptance of natural selection as the sole or even the main agent of whatever modifications may have led up to the existing forms of life. The deepest obscurity still hangs over the origin of the infinite variety of life. Two of the strongest objections to the Darwinian explanation appear still to retain all their force.

I think Lord Kelvin was the first to point out that the amount of time required by the advocates of the theory for working out the process they had imagined could not be conceded without assuming the existence of a totally different sort of natural laws from those with which we are acquainted. His criticism was not only based on profound mechanical reasoning, but it was so plain that any layman could comprehend it. Setting aside arguments deduced from the resistance of the tides, which may be taken to transcend the lay understanding, his argument from the refrigeration of the earth requires little science to apprehend it. Everybody knows that hot things cool, and that according to their substance they take more or less time in cooling. It is evident from the increase of heat as we descend into the earth, that the earth is cooling, and we know by experiment, within certain limits, in what time at what temperatures the matters of which it is constituted, are found to cool. It follows that we can approximately calculate how hot it was so many million years ago. But if at any time it was colder at the surface by 50° F. than it is now, life would then have been impossible upon the planet. And here we can without much difficulty fix a date before which organic life on earth cannot have existed. Basing himself on these considerations, Lord Kelvin limited the period of organic life upon the earth to a hundred million years, and Professor Tait in a still more pænewious spirit out that hundred days at the end of the sun. One of the advantages stand the claims of the geologists and biologists. They have revealed in the prodigious of the clippers which they put at the end of the earth’s hypothetical life. Long cobbled and cabled within the narrow bounds of the popular chronology, they have unwashed expect anew by the readiness. They have lavished their millions of years with the open censured prodigal heir indemnifying himself by present extravagance for the enforced self denial of his youth. But it cannot be gainsaid that their theories require at least all this elbowroom. If we think of that vast distance of time over which Darwin conducts us from the jelly-fish lying on the prime beach to man as we know him now; if we reflect that the prodigious change requisite to transform one into the other is made up of a chain of generations, each advancing by a minute variation from the form of its predecessor, and if we further reflect that these successive changes are so minute that in the course of our historical period—say three thousand years—this progressive variation has not advanced by a single step perceptible to our eyes, in respect to man or the animals and plants with which man is familiar, we shall admit that for a chain of change so vast, of which the smallest link is longer than our recorded history, the biologists are making no extravagant claim when they declare at least many hundred million years for the accomplishment of the stupendous process. Of course, if the mathematicians are right, the biologists cannot have what they demand. If, for the purposes of their theory, organic life must have existed on the globe more than a hundred million years ago, it must, under the temperature then prevailing, have existed in a state of vapour. The jelly-fish would have been disipated in steam long before he had had a chance of displaying the advantageous variation which was to make him the ancestor of the human race. I see, in the eloquent discourse of one of my most recent and most able contemporaries, Archibald Geikie, that the controversy is still alive. The mathematicians sturdily adhere to their figures, and the biologists are quite sure that the mathematicians must have made a mistake. I will not get myself into the line of fire by intervening in such a controversy. But until it is adjusted, I think I am excused for returning a verdict of “not proven” upon the wider issues the Darwinian school has raised.

The other objection is best stated in the words of an illustrious disciple of Darwin, who has recently honoured this city by his presence—that I refer to Professor Welsmann. But in referring to him, I cannot but give, in passing, a feeble expression to the sense of Archibald Geikie, that the controversy is still alive. Professor Romanes, had been taken from us in the outset and full promise of a splendid scientific career.

The gravest objection to the doctrine of natural selection was expressed by Welsmann in a paper published a few months ago, not as agreeing to the objection, but as resisting it; and therefore his language may be taken as an impartial statement of the difficulty. “We accept natural selection,” he says, “not because we are able to understand the phenomena, but because we must—because it is the only possible explanation that we can conceive. We must assume natural selection to be the principle of the explanation of the metamorphoses, because all other apparent principles of explanation fail us, and it is inconceivable that there could yet be any sensible capable of explaining the adaptation of organisms without assuming the help of a principle of design.”

There is the difficulty. We cannot demonstrate the process of natural selection in detail; we cannot ever, with more or less ease, imagine it. It is purely hypothesis. No man, so far as we know, has ever seen it at work. An accidental variation may have been perpetuated by inheritance, and in the struggle for existence the bearer of it may have replaced, by virtue of the survival of the fittest, his less improved competitors; but as far as we know no man or successions of men have ever observed the whole process in any part. There is, indeed, much that is false in observation. Variation by artificial selection, of course, we know very well; but the intervention of the cattle breeder and the pigeon fancier is the essence of artificial selection. It is effects of the action in crossing, by their skill in bringing the right lines of descent together, that progress is made.

But in natural selection who is to supply the breeder? Unless the crossing is properly arranged, a new breed will never come into being. What is
secure that the two individuals of opposite sexes in the primeval forest, who have been both accidentally met and transmitted by inheritance that variation to their successors? Unless this step is made good, the modification will never get a start; and yet there is nothing to insure that step, except pure chance. The law of chances takes the place of the cattle breeder and the pigeon fancier. The biologists do well to ask for an immeasurable expanse of time, if the occasional meetings of advantageously varied couples from age to age are to provide the pedigree of modifications which unite us to our ancestor the jelly-fish. Of course, the struggle for existence, and the survival of the fittest, would in the long run secure the predominance of the stronger breed over the weaker. But it would be of no use in setting the improved breed going. There would not be time. No possible variation is known to us in the short time that elapses in a single life between the moment of maturity and the age of reproduction, could enable the varied individual to clear the field of all contesters, either by slaughtering or starving them out. But unless the struggle for existence took this summary and interminable character, there would be nothing but mere chance to secure that the advantageously varied bridegroom at one end of the wood should succeed in attaining the true theoretical alliance. But unless they did so, the new breed would never ever begin, let alone the question of its perpetuation after it had begun. I think Professor Weismann is justified in saying that we cannot, either with more or less ease, imagine the process of natural selection.

It seems strange that a philosopher of Professor Weismann's generation should accept as established a hypothetical process, the truth of which he admits that he cannot demonstrate in detail, and the operation of which he cannot even imagine. The reason that he gives seems to me instructive of the great value scientific research is running at the present time. I have no doubt many conjectures never entertained any place of knowledge, in preference to making frankly the admission that no certain knowledge can be attained. "We accept natural selection," he says, "because we must—because it is the only possible explanation that we can conceive." As a politician, I know that argument very well. In political controversy it is sometimes said of a disputed proposal that it "holds the field," that it must be accepted because no possible alternative has been suggested. In politics there is occasionally a certain validity in the argument, for it sometimes happens that some definite proposal is so strong or so free from objection. But such a line of reasoning is utterly out of place in science. We are under a obligation to find a theory, if the facts will not provide a sound one. To the riddles which nature confronts us the profession of ignorance must constantly be our only reasonable answer. The cloud of inexplicable mystery hovers over the development, and all more over the origin, of life. If we strain our to pierce it, with the foregone conclusion that the solution is and must be attainable, we shall only for discoveries the figures of our own imagination. Professor Weismann adds another reason for our conclusion, which is characteristic of the time in which we live. "It is incomendable," he says, "that there should be another incapable of explaining the adaptation of panics without assuming the help of a principle of design." The whirr of time assuredly brings its revenges. Time was, not very long ago, when the belief in creative design was common. Even those who were sapping its authority were wont to pay it a formal homage, fearing to shock the public conscience by denying it. Now the revolution is so complete that a great philosopher uses it as a redactor ad absurdum, and prefers to believe that which can neither be demonstrated in detail, nor imagined, rather than run the slightest risk of such a heresy.

I quite accept the Professor's dictum that if natural selection is rejected, we have no resource but to fall back on the mediate or immediate agency of a principle of design. In Oxford, at least, he will not find that argument is conclusive, nor, I believe, among scientific men in this country generally, however imposing the names of some whom he may claim for that belief. I would rather lean to the conviction that the multiplying difficulties of the mechanical theory are weakening the influence it once had acquired. I prefer to shelter myself in this matter behind the judgment of the present living master of natural science among us, Lord Kelvin, and to quote as my own concluding words the striking language with which he closed his address from this chair more than twenty years ago: "I have always felt," he said, "that the hypothesis of natural selection contains the true theory of evolution, if evolution there has been in biology . . . . I feel profoundly convinced that the argument of design has been greatly too much lost sight of in recent zoological speculations. Overpoweringly strong proofs of intelligent and benevolent design lie around us, and if ever particular and living beings, whether near us or far away from them for a time, they come back upon us with irresistible force, showing to us through nature the influence of a free will, and teaching us that all living things depend on one everlasting C6reator and Ruler."
POISONING CASES AND INQUESTS.

ALLEGED DEATH FROM USE OF NOXIOUS DRUGS.

At the inquest, on July 31, on the death of Mary Ann Irish, aged 33 years, wife of an optical case maker, residing at 42, Gaywood Road, Walthamstow, who died on the 28th inst. in the alleged effect of noxious drugs, Dr. Edward Cornish, who made a post-mortem examination, said the cause of death was acute suppulsive peritonitis. Drugs taken in large doses would produce the state of things he discovered. If medical aid had been called in earlier life might have been saved.

Richard Wilson, who had been acting as locum tenens to Mr. Andrews, chemist, of 94, St. Mary’s Road, said that what he supplied the deceased with was sold over the counter every day.

The Coroner: Yes, for a special purpose.

Witness added that he supplied those things prior to the deceased telling him that he had taken anything. He didn’t recommend any of the drugs. He thought that what he supplied was not sufficient in quantity to do any injury. When he heard the woman was ill he took her a bottle of medicine composed of tincture of opium and chloroform water. Finding her very ill he ordered her to call a doctor. He called in a friendly way, and not as a medical man.

The Coroner remarked that chemists had no right to prescribe. He thought further inquiries should be made, and also that the bottles and labels should be produced.

The jury concurred, and the inquiry was adjourned.

—Star.

THE UNRESTRICTED SALE OF CARBOLIC ACID.

On August 2 an inquest was held by Deputy Coroner Taylor, at the Devonshire Arms Inn, Bakehall, on the body of Charles Gregory, aged 42 years, deputy registrar of births, deaths, and marriages. John Roberts Thompson, chemist, deposed that he sold deceased a 6d. bottle of carbolic acid about 11 a.m. on Monday, and he believed the broken bottle produced was the same bottle. Carbolic acid was not a scheduled poison, and anybody could buy a sixpenny bottle without inquiry. Deceased said he wanted it for disinfecting purposes. There was nothing peculiar about the deceased when he came to his shop.

By the Coroner: He regarded carbolic acid as a poison, and it ought to be scheduled. Dr. Fentem deposed that the deceased died from carbolic acid poisoning. Immediately after swallowing the carbolic acid he put his hand to his head and fell forward insensible. By the Coroner: He could have done nothing for him had he seen him when Beere did. Carbolic acid would have the same effect if used externally, and if half that bottle produced was poured over witness’s body it would kill him. It had a peculiar action on the nervous system. He should be drying when found. He regarded it as a scandal to the country that carbolic acid was not scheduled to prevent it being sold. It was the most dangerous poison, and produced frightful death. The deceased had taken opium once, and witness found fault with him. He had been in a very uncomfortable condition of mind, and had complained of trouble at home. A verdict of “Committed suicide during temporary insanity” was returned, and a rider added “That, in view of the many suicides through the use of carbolic acid, a recommendation go to the proper quarters to have this dangerous poison be scheduled.”

Sheffield Independent.

* This name does not appear on the Register of Chemists and Druggists with the address mentioned.

ACCIDENTAL POISONING BY CARBOLIC ACID.

On Tuesday, August 7, before Mr. E. A. Gibson, deputy coroner of Liverpool, an inquest was held touching the death of John Stephenson, aged 8, a house painter, who lived at 22, Edgware Street. It appeared that the deceased was in the habit of taking a drink of beer out of a bottle each Sunday morning, and that his wife usually left the bottle on a table by the side of his bed. The latter had for many years disfigured the house each night, using carbolic acid for that purpose. The acid was contained in a bottle of the same size and practically the same shape as the beer bottle. It was placed on the floor of the house. On the Sunday morning the deceased drank out of the wrong bottle, and soon afterwards expired, notwithstanding prompt medical treatment. Evidence was given to the effect that deceased was a cheerful disposition, and lived on the happiest terms with his family. A verdict of "Death from misadventure" was returned. —Liverpool Mercury.

Correspondence.

THE PATENT MEDICINE VENDORS’ ASSOCIATION.

Sir,—In common with, I suppose, the rest of the trade, I have received a circular from the above. It points out that "all chemists who join us will not be interested," and any chemist who does not join this society will be considered antagonistic to us. I consider this Mr. Editor, to say the least of it, very offensive, in fact, and a species of "blackmail." I am looking forward to the society giving an opinion on the subject. It seems to me this is an effort to break up the Pharmaceutical Society, for those chemists who are prosecuted will naturally expect the Pharmaceutical Society to defend, not the individual see that they are called upon to do so, yet there are those who think this new association ought to be allowed to exist to annoy the legitimate trade. I trust, however, that the "hundreds of chemists" who see sympathy with this association exist only in the imagination of the defence association’s fertile brain. Those will join it (in a moment of weakness, let us hope) fall into a great error. —Yours faithfully.

Obituary.

Notice has been received of the death of the following:—

On July 31, Henry S. Weeding, Chemist and Druggist, West Cowes. (Aged 76).
On August 7, George Galloway, Chemist and Druggist, Inverness. (Aged 82). Mr. Galloway was a subscriber to the Benevolent Fund, and was greatly respected by the whole pharmaceutical community of Inverness.

Answers to Correspondents, etc.

Jos. McDevitt.—Chemists and druggists must exercise discretion with regard to the adoption of the first method. See latter part of section 17 of the Pharmacy Act, 1868, and section 3 of the amending Act, 1876. (Calendars, pp. 80 and 80). In any case there may be certain measure of risk attending the transaction.

Communications, Letters, etc., received from Mr. Gadd, Ince, Junor, Martin, Naylor.
THE PRESENT POSITION OF PHARMACY IN GERMANY.

The twenty-third general meeting of the German Apotheker Verein, which took place last week at Cassel under the presidency of Herr Frölich of Berlin, furnishes an opportunity for placing before our readers some account of the present position of pharmacists in the German empire, and of the views generally entertained by them as to the future of pharmacy in that country. The legislative conditions under which pharmaceutical practice has long been carried on there, differ very widely from those obtaining in Great Britain; but in regard to influences incidentally exercised by change, which have taken place, during recent years, in the general conduct of business, there are, nevertheless, many points of resemblance between the difficulties experienced in the practice of pharmacy in this country and those which are, at the present time, becoming an increasing source of anxiety to our German brethren. For this reason it will be useful to consider the views that are held by them in regard to the general position of the pharmacist, and to describe the endeavours that are being made to conserve and improve that position in accordance with the traditions of the past and modern requirements.

It has been customary to regard the German "apotheker" or pharmacist as a specially privileged individual, necessarily enjoying the advantages of superior education and technical training, protected by the state in the exercise of his calling, and free from the embarrassing influences of trade competition. Those conditions, though highly desirable in themselves, were to a great extent the result of a system of regulation on the part of the State little in accord with the customs or opinions prevailing in this country. The pharmacist has been secured an adequate business by a limitation of the number of pharmacists proportionately to population, and by the prohibition of dispensing by medical men; but he has been strictly controlled in the conduct of his business, and his charges have been subject to legal tariff. As a person engaged in the exercise of a branch of the medical art, his establishment was also subject to periodical inspection by the medical authorities. This system has been in force so long as to have become an accepted custom, and it has been very generally regarded as appropriate and beneficial, inasmuch as it served to maintain the professional position of the pharmacist even in small towns and villages. Modern developments have, however, tended to interfere with the protection thus afforded. The supply of medicinal agents on purely trade lines and promoted by recommendatory advertisements addressed to the public, has gradually acquired such dimensions as to constitute a competition against which the pharmacist is unable to protect himself. Hence has arisen the question whether modification of the existing system is not requisite? This question has long been considered by the government from the point of view of public policy, and by the apothecaries out of regard for the interests of their craft as a means of existence. The tendency of the government is to make the right to carry on the business of an apotheker a purely personal one, and the ultimate result of that tendency would be to abolish the limitation of pharmacies, which has hitherto been a means of protection, in favour of a free trade system, under which suitable technical qualification would be the only condition indispensable for carrying on the business. On the other hand the apothecaries have been concerned with the consideration of what the requisite qualification shall be, and what is to be the character of their business in the future? This is, in general terms, the nature of the question which has now been engaging attention for several years under the name of the "Gewerbefrage."

Another question of equal importance relates to the systematic regulation of the practice of pharmacy, and in regard to this subject there is evidence of a strong desire on the part of pharmacists to develop the practice of their calling far beyond the limits which have hitherto obtained generally. It is contended that, in order to meet all the requirements of the case, the regulation and control of pharmaceutical affairs should be in the hands of a special State department, in which the apothecaries would be represented by members of their own body. This is the subject of "Standesvertretung" which, in conjunction with the "Gewerbefrage," has been for several years a prominent topic in the discussions of the Apotheker Verein and other organisations of German pharmacists. These two subjects have long engaged the attention not only of the government, but also of every one connected with pharmacy in the German empire.

The main features of the present position of pharmaceutical affairs in Germany may be conveniently represented by a brief sketch of the proceedings at the late general meeting of the Apotheker Verein, and especially by reference to some parts of the address delivered by the President, Herr Frölich. The association now represents the whole German empire, and comprises seventy-nine provincial branches, which are entitled to send to the annual general meeting delegates to vote on the questions discussed, and in the election of members of the "Vorstand" or executive body. On the late occasion eighty-six delegates were present, representing sixty-six provincial branches. At the first sitting the association was very heartily welcomed on behalf of the local government officials and by the municipal authorities of the town. Dr. Eendemann, one of the speakers, in expressing the view—derived from long experience as a practising physician—that the relation of pharmacists to medical men must necessarily be very intimate, remarked that in the future, as in the past, the practice of their art, based upon the solid foundations of science and faithful performance of duty would certainly enable them to overcome adverse influences and to survive the political changes which are still to be anticipated. The expression of that view by a medical man was referred to by Herr Frölich as being especially pleasing to pharmacists because of the frequently friendly ties existing between them, and because so many of them fail to appreciate how much the maintenance of the position of medicine is dependant upon its support by pharmacy. In welcoming the foreign guests, the President also spoke of their presence as a satisfactory indication that the desirability of acting together is recognised by the pharmacists of other countries besides Germany.

In the President's address, the support and recog-
nition received by the executive council of the
Verein was referred to as evidence that in its work
it had been duly mindful of the interests of the
whole body. The objection, made in some quarters,
that it had not brought forward any definite measure
of reform and had, in regard to some suggestions
having that object, merely taken a non possumus
position, was deplored by him to have no better
foundation than intentional disregard of fact. He
pointed out that the difficult task of devising
measures for the regulation of a business affect-
ing so many interests could not, in any case,
be performed expeditiously, however great the
desire to make the pharmacy and the pharma-
cist useful, necessary and appreciated fac-
tors of our social organisation. To attempt that
solely from the point of view of the pharmacist
and merely with regard to his material interests
and position would be a mistake. Such a mode of
dealing with this matter he characterised as being
neither possible nor desirable. The failure of the
endeavours made by the government since the
early part of the century, he regarded not so much
as giving evidence of their impracticability as of
the want, in many respects, of any sufficient need
for alteration in the conditions which have hitherto
existed. It has thus been recognised above all, that
from the public point of view, improvement of
those conditions could scarcely be devised, and it
should therefore be the object of pharmacists still
further to justify this indirect recognition of the
fitness of the system hitherto prevailing.

In regard to the future, Herr Fröhlich pointed out
that the aim of the "Vorstand," in the conduct of
the affairs of the Verein was not to provide an
immediate legislative panaceas; but to promote the pro-
gress of the body it represents, in such a manner that
it should keep pace with scientific, technical and
social development. That is very well to be done
within the bounds of the existing system, though its
capabilities are not in all cases so well appreciated
as they might be. It is at least interesting to note
that on the whole the complaints urged against
the German pharmacists are but few. The
government has nothing worse to complain of
than the irregular traffic in pharmacies. That
excessiveness is as much deplored by pharmacists
as by other right-minded persons; but it is
a result of social and commercial conditions, and
of their general development, which is not to be
done away with by pharmacists themselves or even
by the government. The more important question
to be considered is whether the body is progressing
in the same degree as other callings, whether it has
sufficiently kept pace with the progress of science?
In the practice of medicine there has been
immense advance within recent years. Pharma-
cists regard with satisfaction the important and
responsible position which medicine has acquired
in the life of the State. That position has been ac-
quired by improved education. But medicine has
also taken in hand a number of scientific functions
which formerly belonged exclusively to pharmacy,
and it is at least doubtful whether that is condu-
cutive to the public good. The progress of science
is too rapid to admit of its results being appropri-
ated by the members of a single professional
body. The older and more experienced physicians
still rely upon the aid of pharmacists, and they,
without desiring to invade a sphere outside their
calling, must prepare themselves to assist medical
men in such portions of their work as they
are unable to perform in a perfect manner. In
order to do that it is necessary that pharmacists
should stand on the same educational level as
medical men. It is not the fault of pharmacy
that this is not the case, but the fault of the
government. The demand for a higher educa-
tional training has long been urged upon the
government, and it has hitherto met with
steadfast refusal. The reasons given for that refusal
are insufficient, and they continue to be possible
only because the apothecary body has no repre-
sentation in government departments. On the part
of the governmental representatives of medicine,
pharmacists are regarded not only unfavourably, but
with some jealousy—it is feared that when the
apothecary is able to fly he may develop. Here,
again, it may be seen there is an appreciable
recognition of the body. The demand for the
adoption of a higher educational standard must,
however, continue to be pressed, as that is the
only means by which it will be possible to claim
that the control of pharmacies shall be placed in
the hands of persons possessing technical know-
ledge. When that is the case, the pharmacist will
be able to help the physician in a manner very
different from that in which he helps him now, and
by undertaking duties which the physician is
unable to perform, though they are required.

These considerations show that the question as
to the future is not so much one concerning the
development of the material interests of pharma-
cists; but that it is a question what the pharmacist
is to become, and what the pharmacy is to be? That
question cannot be solved by the temporary ex-
pedients which the Prussian government has
adopted in regard to concessions, and it will remain
open until entirely new ground is taken concern-
ing it. According to the view held by Herr Fröhlich
the pharmacy of the future will not be a place for
the sale of specialities, but a hygienic institute
adapted to modern requirements, since that is the
province in which the pharmacist is best of all cap-
able of supporting and assisting the physician. It
will cause no degradation of the physician, but
rather induce an augmented respect for him, if he
has, in the pharmacist, a trustworthy assistant in
his labours.

In the governmental organisation relating to
food supply, a number of questions, which cannot
be disengaged from the question as to whether the State were able to avail itself of the services of
a pharmacist in every small town or village as a
trustworthy person for the performance of the re-
quisite work. That desirable result could only be
 effected by means of a system necessitating better
educational training. The re-organisation, in such
a way, of the conditions under which the exercise
of pharmacy is carried on, so that the State and
the public would be provided with a more highly
educated and more competent practitioner of his
art, would moreover be an approach from a
prospective as to the future of the craft. In conclusion, Herr
Fröhlich appealed to the members of the Verein to
entrust the 'Vorstand' with the duty of endeavou-
ing in every possible way to place their craft in a
position of equality with other professional callings
so that the pharmacist might not stand as a stepson
among the offspring of the sciences.
COUNTER PRESCRIBING.

In a recent number of the Asclepiad, Sir Benjamin Ward Richardson referred somewhat sympathetically to the practice of counter prescribing by chemists and druggists, and recommended that it should be recognized and legalized, a special examination being provided and a qualification granted on its results, which should extend "solely and legitimately to counter practice, never to out-door visiting." This, it was urged, "would define responsibilities and duties in the clearest manner; it would not give the dispenser . . . the right to call himself a registered practitioner of medicine; but it ought to give him the right to dispense publicly medicinal substances with qualified judgment. With the class of men who would by these steps become the pharmacists of this country, the professors of medicine and surgery proper need have no cause for quarrel nor jealousy. They would be highly educated men, occupying a true scientific position; and they would be such able dispensers and professional allies that all who were engaged in practice purely would cease to feel any necessity for dispensing medicines, or for doing anything more than attend the sick and prescribe for them."

Subsequently, speaking at the annual dinner of the Pharmaceutical Society, Sir Dyce Duckworth objected to the views adopted by Sir Benjamin Richardson, and said he would throw down the gauntlet at once to him to come and affirm the doctrine he had propounded in the presence of the Society. He thought he knew how such a proposition would be received, and was quite sure he was the mouthpiece of those present in saying they would all repudiate that recommendation entirely. "He would throw down another challenge, and ask Sir Benjamin Richardson to come and make that statement to the College of Physicians, and he would promise him if he would take a vote upon it he would be left in a minority of one. He felt sure they would all decline to act upon such a recommendation, it was not their work; they knew it was not their work, and did not wish it to be their work. They had something much better to do, and they did it."

By the publication of an article on "Pharmaceutical Apothecaries," in which he reiterates and elaborates his views, Sir Benjamin may be regarded as having accepted the challenge. In the first place several instances are related in which it is somewhat rashly assumed that chemists and druggists "broke the law—when humane motives prompted them in cases of urgent necessity to show that their general training had fitted them for performing, on emergency, other than the functions usually associated with their calling—and it is urged that "the safety of counter practice lies in this fact of necessity." The ordinary chemist and druggist or pharmacist, however, should not be permitted to prescribe until he is legally qualified for the duty and becomes a "pharmaceutical apothecary." A competent examination, it is suggested, might be conducted by a conjoint board formed from the Apothecaries' and Pharmaceutical Societies, the curriculum should include a sufficient measure of hospital practice, and the successful candidates should then be duly registered.

"Another reason" why a new class of practitioners should be created is stated in the words "that the gentlemen who are engaged in pharmaceutical work are becoming aggressive therapeutists," and that the danger accompanying this practice may best be averted by controlling it. "Turn the members of the chemical body that engages in pharmacy into a qualified medical body, that shall find sufficient scope for its skill without breaking out into new and theoretical enterprises which have in them pretence of practical and scientific meaning, without any reality of science. The public requirement, in its natural form, is assistance in emergency or casualty; that the public will have, and if we do not give it what it usefully wants, it will take, in its ignorance, what it does not want, what it deems is useful, but that is not so useful as it might be, and may, from its unskillfulness, be hurtful."

It is extremely doubtful if any chemists and druggists will, upon full consideration, approve of this scheme for bringing them under the control of the Medical Council, yet this is practically what is proposed. The pharmaceutical apothecaries "would, as they now do, perform the minor and emergency duties, would dispense prescriptions, conduct analyses if necessary, and, although in business, would be amenable to medical rule and direction, under the protection of medical rank and registration, and under the supervision of the Medical Council."
PATENTS FOR MEDICINAL COMPOUNDS.

AMENDMENTS of specifications are now published of the following patents for medicinal compounds that have been granted:—5629 (1893) Eye lotion "composed of extract of oelandsia, extract of eyebright, and extract of cayenne pepper;" 0178 (1893) "A medicine for the cure of coughs, colds, hoarseness, and bronchitis, composed of a decoction of liquorice root, Irish moss mucilage, gum arabic mucilage, glycine, chloroform and morphine in the form of chlorodyne, syrup of squills, syrup of marsh mallow, ipecacuanha wine or antimonial wine, oil of aniseed, spirit of camphor, and benzoic acid. A medicinal ointment or jujube may be made by exposing this compound to dry warm air."

EXEMPTION FROM JURY SERVICE.

All registered pharmaceutical chemists who desire to secure exemption from jury service are reminded that it is desirable that they should ascertain that their names are not included in the list of persons liable to serve. The manner in which exemption may be secured when the name is included in the list, which is launched to churches and chapel doors on the first three Sundays in September, will be found described in the Society's Calendar for the current year.

ARSENIC OR POMAIINES?

In a recent case at Handsworth, Birmingham, a child died and several persons were seriously ill as the result, it now appears, of poisoning by ptomaines formed in some potted meat. The first report of the analyst, Dr. MABERY, stated that in the course of the analysis a slight trace of arsenic was found, but at the adjourned inquest it transpired that common zinc containing arsenic had been employed by the analyst instead of the pure article, the excuse given being that the examination was made on Bank Holiday, when the latter could not be obtained.

CONFERENCE PHOTOGRAPH.

This photograph taken of the members of the British Pharmaceutical Conference and their friends, in front of Balliol College, Oxford, is a highly successful one. The grouping on the steps of the College has proved very effective, and the portraits are more faithful than usual. Copies of the photograph may be obtained of Messrs. HILL and SQUIRES, photographers, Oxford, at three shillings and sixpence each.

NEW CONSTITUENT OF THE ATMOSPHERE.

In a recent number of the Liverpool Mercury, J. ALFRED WANKLYN, referring to the discovery of the supposed new gas, remarks that chemists with much practical experience in carrying on analytical operations upon gases will not fail to perceive that the formation of traces of nitrogen oxide, either by the action of the electric spark or of the heated magnesium, would account for everything as yet published by RAYLEIGH and RAMAN on the subject.

THE OXFORD HANDBOOK.

A few copies of this work still remain on hand, and will be supplied to readers who apply for them, but they will not be sent unless the necessary stamps for postage are enclosed, according to the notice on page 76, in the Journal for July 25.
to mixing. For many years it had been his custom to exhaust every other week 1000 lbs. of cinchona bark, and they could imagine the rate of the mixing of the spirit with water; sometimes the spirit was only contained 30 to 40 per cent. alcohol, when there should have been 60 or 70 per cent. Of course economy of spirit was an important point to the pharmacist, especially in these days of high duties, but he preferred heat to hydraulic pressure for recovering it. He was in the habit of making tinctures on a large scale, where large quantities of mace were used, and he found the most economical process was to employ slow percolation, and recover the alcohol by heat. He found it was not possible to exhaust 1 lb. of drug without losing about ½ lb. of alcohol in the process; for instance, in exhausting 100 lbs. of ginger, he lost 23 to 25 lbs. of spirit, 60 to 60 per cent. overproof.

Mr. Conroy agreed with Mr. Umney. His practical experience of displacement was certainly adverse to it. No doubt in the hands of a clever expert good results might be shown; but if left in the hands of a layman, his experience of the admixture of water in the tincture. The process he preferred was hydraulic expression, supplemented by distillation. That was the only process which worked satisfactorily on a large scale. His experience, especially with belladonna, had been very unsatisfactory. The pharmacopoeia process for making an alcoholic extract was to exhaust by alcohol, followed by water, and they all knew that you could hardly get two extracts of belladonna which were alike. On the whole, he did not think this process was practicable, though he felt indebted to Mr. Parker for bringing it forward.

Mr. Hardwick thought, notwithstanding the condemnation which had been passed on Mr. Parker's method as suited for work on the large scale, there must be something in it, and that it was worthy of attention by retailers. Would there be any difficulty from the swelling of woody tissue on the addition of water, causing a block in the filter?

Mr. Martindale agreed with Mr. Hardwick, especially with regard to lin. belladonna and tincture of ginger; he found an expansion occurred when he attempted to displace the spirit contained in the bottle by water as directed. He thought that to some extent by displacing as far as he could, and after getting the quantity of reserved spirit for the next manufacture, watching carefully the specific gravity. The difficulty was that any mixing of the water with the spirit went on so rapidly, and the expansion of the woody fibre in the percolator was such that unless you threw off the top layer you could not sometimes get the process to go on. When it came to displacing proof tinctures, he thought it was better to follow the pharmacopoeia directions, and make up the quantity afterwards, than to adopt Mr. Parker's recommendation. The same with the displacement of proof spirit by water; he thought it was far better to press it out, or where you had the convenience for it, to recover it by distillation; but he found a simple tincture press answered his purpose.

Mr. Smye said the paper was a very interesting one, but scarcely solved the problem how tinctures could be made economically on a small scale. Still, they were much indebted to anyone who endeavoured to accomplish that, because it was very desirable that the pharmacist should make many, if not all, his own tinctures. One of the difficulties was displacement by water, in addition to the swelling of woody fibres that immediately water came in contact with a spirituous solution a certain amount of precipitation
occurred—some resinous matter was thrown down, which more or less filled the interstices of the marc, and practically stopped the percolation until a certain amount of it was removed. The only thing he saw for a long time was the contents of some tinctures in small quantities, he must use an extra quantity of menstruum, and if large enough in quantity, recover it by hydraulic pressure, or if he had only a small screw press, be content to lose a certain percentage of the spirituous liquid which remained in the marc, and so long as he got out the whole of the medicinal principles, considered himself sufficiently insulated enough to justify him in distilling it. He presumed Mr. Umney and Mr. Conroy put it in a still and applied steam in some way, whilst keeping the marc well agitated, as this greatly accelerated the recovery of the spirit.

Mr. NAYLOR said he was very much afraid that the tendency amongst pharmacists was too much in the direction of economy, or to see how far 1 lb. or 1 cwt. of a given drug would go in making a particular preparation, and to be sure that the drug was completely exhausted, rather than to secure the quality of the product. He had been surprised at some degree of surprise that preparations were now being made on a large scale, not in accordance with the directions in the B.P.; whether those products would accord with those made strictly officially he did not pretend to say, but he knew from merely a physical examination of some of them that they were not of the standard required. He would not be surprised to find that such preparations were deficient in aroma, though he did not say they would be deficient therapeutically. Whilst a strong advocate of economical methods, he thought they were bound to obey the methods proscribed in the Pharmacopoeia, unless they were perfectly satisfied that the product they obtained in another way tallied precisely with that obtained by the official method.

Mr. CONROY said Mr. Naylor was entirely wrong in assuming that the two manufacturers he had named did not follow the pharmacopoeia process. That process was strictly followed; as much spirit was obtained as could be by that method, and the tincture was finished, and instead of throwing away the marc, the spirit was recovered.

Mr. PERRY, after thanking Mr. Parker for his paper, said it appeared that he used a cylindrical percolator, and that he should like to have more difficulty in the use of a conical one. With regard to the recovery of spirit from lin. belladonna, making one gallon quantities he found it was almost impossible to recover the spirit with water. For a long time he had abandoned the use of water for the recovery of spirit from such things, and he was hoping when he saw the subject put down that Mr. Parker was going to provide them with some real method for the entire recovery of spirit. From his experience he could not bear out what had been said.

Mr. GROVES agreed with Mr. Parker that the strength of the Haddo percolator would depend upon the strength of the pressure applied. He could not understand how it was that in recovering spirit by means of water a greater quantity was obtained in the case of proof spirit than rectified spirit. One would imagine that the water would sink down and mix with the rectified spirit more easily than with the hexane spirit.

The President said he should like to offer a few remarks on this subject before asking them to thank Mr. Parker for his paper. First, because he was the pharmaceutical son of the man who more than any other introduced the word, viz., the late Henry Deane, and secondly, because he was dismally to criticise the pharmacopoeia process for making tinctures in terms of the mind of which disturbed the editor of the Pharmacopoeia. He still, however, adhered to the fact that the pharmacopoeia process was simply disgraceful as a process of displacement. He was surprised that Mr. Parker had not mentioned osmose. There was no doubt about it that although his theory was that it was a "movement through capillary tubes where the hydrostatic and hydrodynamic effects came into operation," still you were dealing with a dry substance which was formerly in a cellular condition containing moisture in the cells of the plant. Unless he could be satisfied that with a proper proportion of the menstruum, the cells would swell out and produce inside the cell a concentrated preparation. When you introduced the liquid after you had the process of osmose going on between the concentrated preparation inside and the liquid preparation outside, and you must give that time; it was a slow process, not quite the simple one indicated by this movement through capillary tubes. He should be afraid to trust himself, even, to operate with tinctures and use water for displacement, for sooner or later he should probably get into the hands of some person who would not be able to see, and yet tell you what he had done with the Drugs Act, and be told that his tinctures were not of the strength required. There was a process which obtained in old-fashioned pharmacies, where there was a row of black bottles round the top shelf in which the tinctures were macerated, and when they wanted a pint of this, and the first pint was completed, the subsequent intervals the second and the third. Any pharmacist who had anything to do with that process would know that as for securing a tincture which was of uniform strength, the final pint or fraction of a pint would differ very considerably from the first. If he rightly understood Mr. Parker, in making on a small scale, say, a drachm—though he would not recommend anyone to make tinctures on the 5 drachm scale—his method was to put the requisite quantity of drug into a bottle, to add the menstruum to it, and when you wanted a drachm pour it off, and so with the second and third drachm. He did not think that was a process which ought to be recommended or countenanced. Whether you made 4 drachms or 20 gallons, before you used a drop of the tincture it should be a finished preparation. Personally he had a great affection for the shape of percolator introduced by Mr. Deane, which was illustrated in an early number of the Pharm. Journ. He recalled how many papers had followed the directions given in early papers no tinctures which could be made would equal them. You got practically 75 per cent. of the soluble matter wholly extracted in the first 50 per cent. of the menstruum, and then when you dealt with the final quantity when dealing with a very weak menstruum, it did not materially affect the tincture whether you got out one pint less from the menstruum if you made the final quantity up to the full amount for which the ingredients were used. Altogether, while these experiments were intensely interesting, and they were deeply indebted to Mr. Parker, he thought other men with long experience would adopt his suggestions. He hoped there was sufficient literature in existence that if a new pharmacopoeia were going to be published next month a better formula than was in the B.P., or had been put before them to-day, might be adopted.

Mr. Parker, in reply, said he should like to draw attention to the specimens he had brought with him indicating a comparison between upward and downward displacement. He had the fifth, sixth, seventh, and eighth percolates of the two systems, showing where the line between tincture and water occurred. The third time ago he had found the lines. The two series were almost identical, proving that upward or downward displacement made no difference in the
the process if properly conducted. That proviso was rather important—the "if" came in everywhere. He might say, in answer to Mr. Martindale, the President, and Mr. Naylor, that he prepared according to the B.P., and he desired to give the precise statement that was all the statement on a good many labels. "Prepared by a careful pharmacist" would be a much greater guarantee of the product. The instructions might be followed intelligently and carefully, or otherwise, and it was plain enough that a careful pharmacist, or an uncareful one, might follow any process he adopted. If it was not satisfactory he would be aware of it. The origin of the paper was his own process. For many years he had a suspicion of displacement by water under any conditions, but thought it was altogether too heterodox for a modern pharmacist to profess to make any use of that method in the preparation of lin. belladonna and tr. zingib. fort, where a large proportion of marc and a comparatively small amount of menstruum was employed. He always acted on three series of percolates, and first made one batch of tincture amounting to 40 ounces. When that had passed through and received, and then a third. The next time he wanted to make a tincture he should pass through the ginger root first his second percolate, which would then be collected as the final product, afterwards washing it through again with successively increasing lengths of time until the spirit was extracted out; the only difference was in the fourth place of decimals, that not only with rectified but with proof spirit. He had demonstrated that in four or five proof spirit preparations, but he did not recommend the process for proof spirit tinctures generally. The loss was generally considerable; in tr. rhinehemo co. he recovered 75 per cent. out of 80. He would be pleased to hand Mr. Naylor a specimen of the tr. rhei, and ask him to get half-a-dozen other specimens and compare them. The crucial point of Mr. Naylor's criticism rested primarily on a misunderstanding of both Mr. Umney and Mr. Conroy, and he could not imagine how he fell into the error. It was perfectly clear to him that on the manufacturing scale, which those gentlemen referred to, the finished perfect tincture was first made, and the matter of applying heat for distillation was simply for the recovery of waste spirit from the marc. Great stress had been laid on the importance of rectifying all operations, but in his opinion it was not so much following the instructions as following them intelligently—it was not the following but the intelligence which made the variation in the result. He maintained that if you had four pints of tr. rhei to make, the most perfect system of getting a uniform product under twenty different manipulations would be to put the whole of the ingredients, including the menstruum, into a bottle and shake it up until no more could be extracted. Samples then taken from the whole would be fairly equal, whereas taking twenty different manipulations and telling them to follow the B.P. process, following with the fourth quarter, then pressing the marc and making up afterwards, would leave a very wide margin for variation in consequence of the amount which was wasted in the process. That would reply to the President's criticism. As he was making of ochra, he had no call for tincture of saffron, and if he had a prescription containing onederachm he certainly not make a pint of tincture of saffron for that purpose. If the pharmaceutical process for making one pint were simply to put sufficient spirit into a bottle, and shake for two days, and pour off when undisturbed, the product must be uniform. Then he could make his drachms, put it into a bottle, shake up, and
SECOND DAY'S PROCEEDINGS.

On Wednesday, August 1, the Sessions of Conference were resumed at 10 a.m. The following was the first paper read:—

LABORATORY NOTES.

BY F. G. J. BIRD.

Potassium Stearate in Turpentine Liniments.

The compounds of stearic acid with the stearates possess in a high degree the property of forming gelatinous solutions with water, the presence of a very small proportion of dissolved stearic acid being sufficient to render a liquid almost solid.

It was thought that this might be turned to account in the preparation of a liniment containing turpentine and ammonia as its chief constituents, which, after repeated trials with sapon molla, had proved unsatisfactory, and had invariably separated. Potassium stearate in solution was at first used, but with little success. When, however, stearic acid was dissolved in the turpentine, and the mixture of ammonia and steaic acid was added, it instantly produced a milk-white emulsion of admirable consistence, and showing no tendency to separate. In this case the large excess of ammonia exerted no disturbing influence, but appeared rather to increase the emulsion power of the stearate. The proportion of stearic acid necessary for the purpose was found to range from 1 to 2 per cent., according to the amount of water present, increased water requiring a larger proportion of stearic acid. The acid should be melted in a water-bath, a little turpentine added, the mixture warmed till clear, and then poured into the remainder of the turpentine.

The same process may be applied to the preparation of Lin. Terebinth., B.P., the formula for which would stand as follows:

Lin. Terebinthina.

Oil of Turpentine ............. 16 fl. oz.
Camphor .................... 1 fl. oz.
Stearic Acid ................. 80 grains.
Solution of Potaash .......... 4 fl. oz.
Distilled Water ............. 16 fl. oz.

Melt the stearic acid with a little of the turpentine on a water-bath, and add to the remainder in which the camphor is dissolved. Also sulphuric acid solution of potash and distilled water in a bottle of sufficient capacity, add the turpentine solution, and shake vigorously for a few seconds. The result of this formula is a milk-white liniment which is always of uniform consistence and does not separate. It is advantageous in the cooling of the malpighii, and also facilitates the action of the liniment in the chest. The proportion of stearic acid required to effect the emulsification of the turpentine, and the ease and rapidity with which the liniment can be prepared, are additional points in favour of this formula. One grain of stearic acid requires about 3 minims of liq. potasae for neutralisation. This corresponds to the formation of the neutral potassium stearate, and is the proportion which requires to be added with oil. terebinthina, as it has been shown that with the official process, slight variations in manipulation, even with the same materials, will produce widely differing results, by working in several different ways with stearic acid I have not succeeded in altering the character of the liniment.

Distilled Water.

The quality of the distilled water used in pharmae has from time to time given rise to much discussion, which, at all events, has had the effect of dra
attention to the very unsatisfactory condition in which this article is often met with. Distilled water containing ammonia is very prone to develop fungoid growths, and there are many apparently obscure cases of fermentation and decomposition causing much trouble and loss which may be traced to the presence of small particles of organic remains and fungic germs as impurities in the distilled water. The subject merits more attention than it usually receives, as organic matter of this description is almost more objectionable for many pharmaceutical purposes than inorganic salts.

A still of large capacity was formerly necessary to furnish sufficient distilled water for average requirements, but the small stills on the continuous principle, which have of late years been placed on the market, are far more convenient in use, and need but little attention. Evidently, in a continuous still, the first portion of the distillate cannot be rejected, and the product will always contain a small fraction of the original acid and fresh water, and the still to retain it. To effect this, and at the same time destroy organic matter and nitrates, various substances have been proposed, such as alum and potassium permanganate, sulphuric acid, phosphoric acid, potash and permanganate of potash, and nitric acid solution on the still. This last combination is the most effective with a second-rate water, but the distillate always acquires a peculiar odour, which for certain purposes is objectionable. With the view of avoiding this odour if possible, I tried the substitution of potassium bichromate for the permanganate, and obtained a distillate which was colourless and answered the pharmacopoeia tests. Suitable proportions for use in a continuous still are 10 grains of bichromate and 6 fluid drachms of sulphuric acid for each gallon of the still's capacity. With water from the London mains, sulphuric acid alone, or even oxalic acid, will furnish a very pure water, which, if properly kept, never becomes cloudy or develops fungoid growths.

A microscopical examination of samples of distilled water containing fungoid growths will also show small particles of vegetable tissue, introduced as dust, which have formed nuclei for the growth of bacteria. The appearance of fungi in distilled water is generally attributed to ammonia in solution, but they probably quite as often arise from the fragments of vegetable débris, always to be found in the dust of a pharmacy, which form a weak infusion very favourable to their development.

A useful form of vessel for the storage of distilled water consists of a large glass bottle with a Stoneware tap and narrow neck, the latter being plugged with cotton wool and surrounded by a loosely-fitting tin cap. Storage tanks constructed on this principle prevent contamination by the odour of ammonia unless a perfectly fresh and clear condition, however warm and unfavourable the situation in which they may be placed.

It is a well-known fact that syrups hypophosphit.

was made according to the formula of the B.P.C., and all sometimes develop a sulphurated odour. Various formulas have been assigned for this, such as the use of sugar bleached with sulphurous acid or faced with linseed, and the presence of sulphuric acid or phosphates which become reduced by the free hypophosphorous acid in the syrup. Certain it is that all the more volatile water, a want of unpleasant odour, and it is only safe to employ pure sugar which has neither been bleached nor intentionally coloured.

A sample of this syrup came under my notice some weeks ago, which, although prepared with pure sugar and a solution of hypophosphite of iron free from sulphate, still possessed a disagreeable smell. On testing the syrup an excess of sulphates was found to be present, and an examination of the other ingredients revealed the fact that the hypophosphites of calcium, manganese, and potash all contained sulphate as an impurity. I have not yet found a commercial sample of either calcium or manganese hypophosphate entirely free from sulphate; many specimens contain a considerable quantity. Evidently very pure salts must be used, or the alternative, and perhaps more convenient, plan may be adopted of dissolving the hypophosphites of calcium, manganese, and potash in the iron, quinine, and strychnine solutions, and after proceeding farther with the formulae precipitating the sulphate by the careful addition of a strong solution of barium hypophosphate.

Repercolation as a B.P. process.

The process of repercolation, although a favourite one in American practice, and used to a fairly large extent on the manufacturing scale in this country, has not as yet obtained official recognition. This has been doubtless due, not to any want of appreciation of pharmaceutical progress by the compilers of our national pharmacopoeia, but to a laudable desire to give an adequate trial of the process until extended trial had proved its superiority over present methods. The time has now arrived, I think, when the question of its adoption should receive careful consideration, as it may be applied with advantage in two at least of the formulae of the British Pharmacopoeia, viz., ext. cocc. liquid. and podophyllin runa.

As a general process it has disadvantages which are not as a rule put forward very prominently by its advocates. The chief of these is the necessity of storing a large number of weak fractions or percolates. This may be of no moment in a manufacturing house where fluid extracts are constantly in progress, but it becomes a matter of consequence to the small pharmacist, who may make such extracts at infrequent intervals, and who does not wish to add an accumulation of unfinished preparations to his already overburdened shelves.

The ordinary official process, carefully conducted, is, in my opinion, preferable for working many drugs on the small scale, but when dealing with considerable quantities, repercolation is superior in economy, and frequently in excellence of product. With respect to the two formulae mentioned, it presents distinct advantages. The official formulae for ext. cocc. liquid. directs the powdered leaveds to be percolated with proof spirit until exhausted, the first portion of the percolate reserved, the spirit distilled from the remainder, and the residue evaporated to a soft extract, which is to be dissolved in the reserved portion, sufficient proof spirit being added to make the product up to the required volume. As prepared in this manner the extract, although brownish green when first made, gradually loses its green hue and throws down a heavy deposit. This may be attributed to a partial alteration of the constituents of the leaves by the heat of distillation, and possibly to a little water introduced with the soft extract when dissolved in the reserved percolate. Either alcohol or water, even in small proportion, precipitates ext. cocc. liq., so that if the alcoholic strength be disturbed, deposition may be expected. The change in colour is accompanied by an alteration in the behaviour of the extract when diluted with the soft extract, the product being in consequence most undesirable in a pharmaceutical preparation.

When the same extract is made by repercolation no deposit is thrown down, even after many months keeping, and this alone should prove a strong recommendation in favour of the process. Comparing the two methods, the most noticeable difference is in the specific
gravity of the product, which in the B.P. process generally comes out somewhat higher, the average being about 1010 as against 1004 by repercrolation. But as the former deposits on keeping this difference is not so important.

The details of the process which I have found to work well in practice may be of interest. Six percolators are a convenient number to use, although it is quite possible to work with four. The powdered drug is divided into as many equal parts as there are percolators, and by depositing 6 lbs. in each percolator on, 1 lb. is uniformly moistened with 16 fluid ounces of proof spirit and passed through a moderately coarse sieve. The orifice of the percolator having been plugged with cotton-wool, and a layer of clean silver sand placed upon it, the moistened drug is introduced, and a sufficiency of proof spirit poured on to saturate the sand and leave a stratum of liquid above it. The whole having been allowed to macerate during twelve hours, percolation is allowed to proceed slowly. The first 16 fluid ounces of percolate are collected separately and used to moisten the second lb. of coca leaves. This operation is repeated for each percolate, and at the first 16 of each percolate a specific gravity somewhat higher than that of the finished product. For coca this would be about 1010, and is generally reached when the extract has passed through about the third or fourth percolator. This percolate is set aside, the second 16 fluid ounces being used to moisten the drug for the next percolator, and the same procedure is followed for the remaining percolators. From the last one sufficient percolate is collected to make with the percolates already reserved 92 fluid ounces in all, and afterwards as many fractions of 16 oz. each as may be necessary to completely exhaust the drug. An allowance of 4 fluid ounces is made in the product to compensate for the extract in the weak percolates collected for a subsequent operation. When starting with weak percolates in hand, the strongest is used to moisten the contents of the first percolator, and the others poured on in succession; in this case the full quantity of product is obtained.

The process for podophyll resin is another in which the avoidance of heat is undoubtedly advantageous. Much has been written on the deviation of the podophyllin resins of commerce from the B.P. characters and tests, and although this has been shown to be true in many instances of adulteration, and in others to the employment of different processes, it has also been stated that the B.P. requirements are too exacting, and that it is very difficult to obtain a resin answering the B.P. tests by the official method. With this latter statement I entirely agree. An examination of a number of commercial samples, certainly gives one the idea that manufacturers experience some difficulty in the matter, for it is quite the exception to find a sample which is completely soluble in rectified spirit and in ammonia. Many form a clear solution with ammonia, and only partially dissolve in rectified spirit; I have also met with samples labelled "British Pharmacopeia" which dissolved in spirit, but left a flocculent residue when treated with ammonia.

The process of the pharmacopoeia when modified by substituting repercrolation for the present method of preparing a tincture and removing the alcohol by distillation of the product which is completely soluble in rectified spirit, in solution of ammonia, and in aromatic spirit of ammonia. The podophyllin rhizome should be in No. 80 powder, and a fluid extract prepared from it of a strength equalising two parts of the drug in one fluid part of the extract. This, having been rendered perfectly clear by decantation or filtering, should be poured into three times its volume of iced cold water, the remaining directions being followed as they stand. 100° F. is a suitable temperature at which to dry the resin.

A sample prepared in accordance with the above answered the B.P. requirements in every particular. The per cent. of the resin in the rhizome, with a tinting of green; and the yield 3½ ozs. from 6 lbs. of rhizome, equal to about 4·3 per cent.

Mr. Joseph Ince said it was very desirable to have a process which would give uniform results in the case of liniments, and if the one recommended would do so it would be a considerable advantage. With regard to the preparation of emulsions and the two liniments mentioned which strictly came under that heading, it was known to every pharmacist that the formula for an emulsion went for comparatively very little in the light of its ultimate success, and the manipulation was equally important with the formula itself. It depended quite as much on tact and delicacy of manipulation as on the formula, and it would, therefore, be a great advantage if any method could be introduced which would avoid that uncertainty, and secure a more uniform getting of these preparations in a uniform condition. All these soap liniments depended on the emulsion being prepared by means of soap as a basis, and it literally depended on the operator what turned out. Two experienced manipulators might stand side by side with the same ingredients, and the two would produce emulsions of a totally different character—one would be gelatious and the other much more fluid. If there were sufficient skill in the operator the present formula would answer very well, but after all it was the dispenser who was due the excellence of the preparation. With regard to the small still in continuous action, he did not think many pharmacists were aware of its great advantages. Many were under the impression that if they wanted anything in appreciable quantity they must have a large apparatus, but there were excellent stills now which worked remarkably well, and comparatively large results might be obtained by the continuous process, particularly in the case of distilled water. In his own small practice, for educational purposes, he had a small still with the continuous process, and by the addition of a little sulphate acid he produced a distilled water which was all that could be desired.

Mr. Jones said he was particularly interested in the sample of emulsion of tarpentine, because he believed this process could be put into a number of hands, and would give a uniform result. He showed some years ago at the Midland Counties Association, that an almost precisely similar emulsion could be made by using oleic acid, and the formula would be found in one of the Year Books. The only difference here was that Mr. Bird used stearic acid, which certainly had the advantage that it could be had in a greater state of purity to start with. At that time he tried various brands of oleic acid, and found practically there was no difference between a very cheap article and a more expensive one, and as he was prepared to admit that stearic might have an advantage. He should like to ask whether the emulsion was perfectly inseparable? His emulsions was practically inseparable, but not really so, because after being kept for a month it would show a milky layer at the top of the emulsion, and this might easily be formed by shaking. If Mr. Bird's emulsion showed no separation at all in a month the process might be looked upon as being as near perfection as could be expected.

Mr. Linford said he had worked the process published by Mr. Jones, and by carefully testing the amount of potash necessary to saturate the oil before making it, it made a perfectly inseparable
A linen, which he had been standing for six months.

With regard to repercolation, for the last ten years he had a series of stone cylinders filled at the bottom with a bag, a glass tube, and a screw stop. He had found a way to add the slight traces of soda, especially with clays, by making a fine powder, stopping the bottle with fine cotton wool and sand, and regulat- ing the flow to about ten drops a minute. Passing the whole through six percolators, one after the other, he found it answer very well. He had a shelf above this, in the second percolator, with the first percolator was passed into a bottle with a glass tube from it, which just dipped into the fluid in the second one, so that it was going on constantly day and night. Very many substances he had tried in this way; he had found to be almost absolutely excluded, even in the second percolator. He had used the process also for fluid extracts of ipecacuanha, and for several concentrated infusions, notably those which depended on the aromas of the drugs, and found it much superior to any other method. This was the result of ten years experience.

Dr. Syme gave with reference to the syrups of hypophosphites his opinion. He showed that the unac-cepted odour developed was almost entirely due to the colouring matter, ultramarine, used by sugar writers to cover the slight yellow tinge of refined sugar. Sugar should be used in which this colour was Ced also. It should be tested separately, it could be easily tested by taking a portion of the solution of repercolate sugar, fife, when the blue deposit would appear on the surface if it were present. By avoiding this, you avoided the chances of the decomposition he referred to and were able to see what quality of sugar you had. The more imperfectly refined sugar always had a larger quantity of blue.

Mr. T. E. Man said he could emphasise the remarks of Syme. He had had a good deal of experience, and had learnt much from the criticisms of pharma- ceutical writers, particularly Professor Symes of Edinburgh, who had written in his text-books, particularly Professor Symes' "Pharmaceutical Chemistry," that to find a description of the process there was a justification by the formula and the equation, but he could say that the equation did not represent actual results. The sulphates appeared from two or more sources. First there was the fact that the phos- phate of barium always contained a little sulphur, and the other was that the hypophosphites were not true sulphate. The water used was not even the distilled water, for there was not very much of it in the place where a good deal of the hypophosphites were made. The volume of liquid used, including the necessary decomposition and re-crystallisation, involving thousand of gallons of water generally used in the process, so that there were possibilities of sulphates here which could not be easily managed. Nevertheless, the fact remained that occasionally up of hypophosphites made by even the best methods were complained of on this account, and it was a matter to be very careful in making a solution of barium hypophosphite in solutions. Young chemists especially were the impression that barium was one of the most things to get out of solutions, but let them get it out of a solution of hypophosphite. It had never been able in a solution of hypophosphites even moderately dilute to get the exact point at which the barium was just enough to remove the solvent. When you removed the solvent the next complaint was you had a very small quantity of barium. Some operators observed some precipitate like a trace of barium at the smallest traces of sulphate. He did not say it was impossible to get them out, but under ordinary manufacturing conditions on a very large scale it was a difficulty which skill, science, and experience alone could solve. His advice was—Beware of the sugar!

Mr. Unney desired to thank Mr. Bird for bringing forward this matter of the compound syrup of hypophosphites, because it was considered necessary to overhaul the formula which had been published, which was not as perfect as it might be. Mr. T. E. Man, as a manufacturer of hypophosphites, spoke with authority, but he had not learnt much from him, and, with reference to what Dr. Symes said, strange to say, he went to Liverpool for his sugar and bought unblued sugar warranted made from cane, and yet he got the odour complained of. Dr. Symes might shake his head, but he had constant complaints that this syrup smelt of sulphured sugars, or whatever it might be. He had thought it was whatever it was not due to the sugar, and was rather inclined to think that it was more due to some impurity in the hypophosphites. He hoped his colleagues on the Formulary Committee would see if they could not improve the process. As to the possibility of hypophosphites being used for the manufacture. Twenty-five years ago he recommended repercolation of cinchona bark; one could start with water and get to a gravity of 1-050 at the end with repercolation.

Mr. L. L. Mills said that during the last seven or eight years he had made considerable quantities of syrup of hypophosphites. He always made the solution separately, mixing it with the syrup as required. He had never had any odour from the solution, even when kept a considerable time. He always used sugar he could warrant free from blue of any sort, generally Martinique's English made. Mr. Comber said he could confirm what had fallen from Mr. Unney. Probably the sugar he used was the same, and was absolutely free from blue, but he must say, although they made syrup from that sugar which was made specially for the purpose, still they got this odour. He could only attribute it to hypophosphites themselves. He could confirm what Mr. Bird said, and he did not think it was at all due to the sugar.

Mr. Parkes said this seemed to be a game of shuttlecock and battledore between the ultramarine of the sugar and the impurities in the form of sulphates. The probability was that both of these sources pro- duced sulphured hydrocyanic, but his own opinion was that the great bulk of the danger remained in the sugar. There might be danger from sulphates among the hypophosphites, but if you steered clear of sulphur in the sugar you got rid of a great deal of the difficulty. He had found himself, from experience of sulphured syrup, that if he had used the purest sugar he could buy he had never had a sample which had this unpleasant odour, although in preparing a chemical solution he always erred on the side of having a trace of sulphuric acid left rather than any barium.

Mr. G. E. K. thanked Mr. Bird for having got rid of many difficulties. Little by little, he had always been a worry to the student, to the examiner, and even to the experienced pharmacist, the difficulty being that the soap was so variable. He had here given something definite, stearic acid and solution of potash, both definite bodies, and by the use of them they were likely to get definite results. He hoped the preparation kept well in the condition of emulation, though he would not go so far as to say that it should
be condemned on account of a slight separation. The present preparations were by no means satisfactory, and if this were found to be what it was represented he had no doubt it would be introduced into the British Pharmacopoeia. The liquid extract of coca had recently given him a certain amount of anxiety. He had a prescription to dispense containing it, and it was noticed that it contained a considerable amount of precipitate. Of course it was sent out with the usual “shake the bottle” label, but shortly afterwards brought back with the whole of the chloroform volatilized and strongly tainting the sides of the bottle. It was suggested that something was wrong either with the dispensing or the prescribing, but it was soon found out that there was nothing particularly faulty with either. One could not tell exactly what was going to happen in a new combination, but on repeating the prescription again with a fresh preparation it gave precisely the same result. If they could get rid of this colouring matter from any of the extracts it would be a great advantage; they did not want it there, it was useless and nasty, and gave rise to complaints. Perhaps in this liquid extract of coca there might be some difficulty from the use of heat, and if they could get a very satisfactory extract without the employment of heat it would have advantages over one prepared with proof spirit.

Mr. Penny said there was one drug to which the process of repercolation could be adapted by retail pharmacists, viz., senna. Dr. Clarke called attention to it some years ago, and he had been in the habit of preparing it by repercolation, and got a very admirable product. The leaves were readily exhausted, and he would refer members to Dr. Clarke’s paper.

Mr. Bred, in reply, said he was well acquainted with Mr. Jones’s process for making turpentine liniment with oleic acid, which was a very admirable one, but in his experience he found it separate. It might be due to want of adjustment between the quantity of liquid potash and oleic acid. But with stearic acid any quantity between 20 to 30 of liquid potash to 10 of stearic acid would be satisfactory. There were two stearates, an acid, and a neutral. As to the syrup of hypophosphites, he was of opinion that both sugar and sulphates were the cause of the sulphured odour. He might add with reference to the liniment, that it did not separate in the least, being kept for weeks, which was as long as his experience extended over.

The following paper was next read:

**Note on Extract of Malt with Cod Liver Oil.**

By H. W. Jones, F.G.S.

Extract of malt with cod liver oil is popularly supposed to contain as much oil as an ordinary emulsion, that is, half its bulk.

To ascertain how far certain advertised preparations conformed to that standard, I selected four well-known brands, which I judged to have the largest sale. The method of assay was as follows:—Five grammes was dissolved in 50 C.c. of water, placed in a stoppered glass separator, and 50 C.c. of ether added. After standing till the ether containing the dissolved oil had separated, the entire upper layer with flocculent matter (a small quantity of emulsified ether and extract) was separated from the clear layer of malt solution. This latter was washed with C.c. of ether, and the combined etherol solutions allowed to evaporate spontaneously in a glass dish with upright sides. The residue was dissolved in ether, to separate the small amount of extract, dried in a water-oven after evaporation, and finally weighed.

The following table gives the percentages obtained:

Samples made with 50 per cent. by volume were obviously compete unfavourable with those containing less oil, and would have a tendency to show greater rancidity. If not actual separation of oil. As a matter of fact, I know any instance where sample “D” was selected for continued use, as it was regarded as the most palatable preparation which could be procured.

Mr. Alock asked if Mr. Jones could give the origin of these things more definitely. It was high probable that the sample was a small quantity of oil, come from what they knew as “stores,” and that were the fact, it would be well that the we should know how pharmacists had to compete against the most dishonest practices. With regard to the process, he would ask if he succeeded in separating the flocculent portion from the etheral layer? I found in the analyses of those emulsions that a Berner Schmidt method adapted for the examination of milks for fat was very useful for emulsions. It was very difficult sometimes to get the whole of the oil from the flocculent layer.

Mr. Unvev said he hoped, when he saw this matter was coming before the Conference, that they would have a little light thrown on the subject, but, unfortunately, Mr. Jones seemed to have dropped the matter when he ought to have gone on. He showed the great variation in trade samples, which was to be expected, insomuch as there was no authorized formula for their preparation, but that was all. It was quite clear that this matter should be taken up by the Formulary Committee, and that they should decide whether a 10, 20, 30, 40, or 50 per cent. mixture of these substances was desirable. If Mr. Jones had made experiments in that direction, said that in his opinion a 10 or 20 per cent. mixture was desirable, they would have had some real information. He had seen considerable quantities of this extract prepared. It could be made by two methods; first, by mixing oil with the extract; mechanical means, and, secondly, by using some body as pure gum arabic, and there again he hop Mr. Jones would have given them the benefit of an experiment as to which method was the most desirable for preparing this body, which was not an emulsion, strictly speaking. The public liked it, evidently believed they obtained benefit from a mixture of these two substances, one being a feeding substance and the other a valuable medicine, and therefore the sooner the Formulary Committee decided what the strength of the mixture should be and how it should be made, the better. He must he was horrified to find there should be such a dilute as 1-2 per cent. in one case, and in another 25 per cent. His own idea was that the bulk of the extract contained between 10 and 20 per cent. of oil.

Mr. Conroy agreed that the Formulary Committee should take up this matter. His impression had been that cod liver oil and malt contained 20 to 25 per cent. of oil. Many years ago it was made containing much as 50 per cent., but that was never obtained now.
as far as he knew. As generally sent out by the wholesale trade it contained 25 per cent.

The President said he agreed with what had been said, that Mr. Jones had stopped short at the most interesting point, and he hoped he would continue his researches. It was important to know, with all due respect, the nature of nitros ether to be something or other, what their constitution was.

Even when analyses were published in the medical journals, and copies were affixed to the vessel or pot, stating they contained this or that, they were often delusive. It had become his present practice, before receiving a label stating that it contained 15 per cent. of moisture, on analysis proved to contain 30 per cent., so that it was not at all peculiar to malt and cod liver oil. The same principle ran through the whole gamut of advertised nostrums, and as medical men seemed to prescribe these nostrums for their patients, they certainly did want formulæ on a scientific basis, and he had no doubt the Formulary Committee would take notice of it.

Mr. Jones, in reply, said he had made some experiments, but was not yet in a position to say how one could prepare 60 per cent. oil and get a preparation which would keep six or nine months, but he was certain people would keep it for a long time. With regard to the proportions, he should prefer, if possible, 50 per cent. On the Blue List there was formerly the question with reference to malt extract itself: Why did it go solid? But he supposed everybody knew now, as it did not appear on the list. The method recommended by Mr. Alcock was very good for separating fat, but he found the best way was to divide it into two parts, first to allow the ethereal layer to separate completely, which in some cases took two days, and run off the lower layer through the stopcock. Then run off the entire ether and the entire flocculent layer, evaporate the whole down, and redissolve. By that method there was no chance of leaving anything behind, or getting anything out that was not there. With regard to mixing by mechanical means, he remembered reading in one of the journals an answer to a correspondent: "You cannot expect to make a very fine cod liver oil and malt preparation; you cannot compete with what you buy, because the manufacturers spend thousands of pounds on having the most perfect mechanical mixers. He did not think that was required and knew you could make it with any common pestle and mortar. The first extract of the right consistency and ordinary oil. You could make a 50 per cent. emulsion, but it would not keep, and he did not believe an expensive apparatus would make it keep any better.

The next paper was on—

THE KEEPING QualITIES OF CERTAIN SAMPLES OF SPIRIT OF NITROUS ETHER.

By H. W. Williams Jones, F.C.S.

The most deterioration of spirit of nitrous ether under suitable conditions of everyday use is well known, and has been commented upon by a number of observers.

To test the keeping qualities, under specially good conditions, I set aside a number of samples in January and February last year (1873). The stoppers of the bottles were inserted down, tied over with leather, and placed in a box which remained undisurbed until they were finally examined.

The loss of ethyl nitrite was considerably less than anticipated, and is shown in a tabular form. Column gives the number of C. of nitric oxide yielded by C. of the spirit when received, and column II. the fall of gas after keeping for the time specified.

Since testing my samples I find that similar, though not quite identical, results have been recorded in the last (1894) edition of Squire's 'Companion to the British Pharmacopoeia.'

The editors of that volume say: "Dymond (Ph. J., 167, 467) states that nitrite of ethyl in rectified spirit decomposes from there being so much water in it, and that this is likely to account for loss of strength on keeping. Our experience scarcely agrees with this. When evaporation is prevented we do not find the loss to exceed 6 per cent. (32 C.C. of gas from 5 C.C. reduced to 30 C.C.) in a month, and believe evaporation to be the chief cause of deterioration."

Now, however true it may be that the loss of ethyl nitrite is mainly due to evaporation, a distinct loss, in all probability due to the water present, is observable in all cases; and a very notable change is apparent in the only sample (No. 9) amongst those procured, which exceeded the limit of specific gravity given by the British Pharmacopoeia.

Mr. Groves said if Mr. Jones could give them some idea how to keep nitrous ether without deteriorating, they would thank him very much. They all knew this spirit was liable to deterioration, partly owing to evaporation, and partly to temperature. He presumed the bottle was practically full, so that the contact with air was prevented.

Mr. Simpson said his experience was that if this substance was kept in stoneware bottles at a low temperature, or in coloured or black bottles, it was less liable to change than in ordinary white bottles.

Mr. Srsby said he had kept some samples for a considerable time, except that instead of being the loss of nitrous ether he found that there was a loss of this it was an ethyl nitrite prepared by a process modified somewhat from Duncan's. Samples were prepared in February, 1893, and the results of testing, though not very systematically, were very satisfactory. He tested it in November or December, after it had been frequently opened, and the bottle was only half filled, and it then gave 30 volumes of gas from 5 C.C. The samples were stored in a similar condition to Mr. Jones's, in a light cellar with no direct sunlight. Additional precaution might be taken by those storing the spirit by smearing the stopper with a mixture of hard and soft paraffin of about 3 to 1, which greatly prevented the diffusion of gas through the stopper.

Mr. Umney said the father of the pharmacopoeia process was the late Professor Redwood, and most of them at Bloomsbury Square had heard him harangue over and over again on the merits of spirit of nitre. He always contended that it was not ethyl nitrite alone which was the medicinal agent in spirit of nitre, but that alcohol and other bodies were equal medicinal factors. Unfortunately, Professor Redwood was gone from them, and since his

* The only sample met with below "B.P." sp. g
The method between one and the other, but the greater amount of moisture present greatly accelerated decomposition. His attention had been drawn to the case of a chemist who was prosecuted for the sale of sweet spirit of nitre, which had a specific gravity of 1.850, of which 8 C.C. gave only a definite solution of ethyl nitrite which could be made of a definite strength. He could not say the preparation would keep, because it was as natural for ethyl nitrite to decompose as it was for iron to rust. The pharmacopoeia recognized that, as it gave a maximum and minimum strength. It was hoped that it would come to be regarded as a spirit of nitre which should be definite in composition at all times. If they could not discard the old preparation, at any rate they might have a new one side by side with it.

Mr. Linford said he made spirit of nitre some time ago by the ethyl nitrite process, but constantly had it returned, as it was not the spirit of nitre people were used to.

Mr. Wright said there was a very good reason for the complaint. Mr. Linford said his firm had had from time to time. He was quite sure that if any pharmacist who had been in the habit of selling the old-fashioned spirit of nitre, and in a manner of spirit made according to the pharmacopoeia, he would soon have some of it returned on his hands with similar complaints. They were all aware of the fact that sweet spirit of nitre was employed very largely for domestic purposes, and amongst other things for producing a diaphoretic effect, and, according to his experience, when the spirit made from ethyl nitrite according to the 1867 and 1885 pharmacopoeias had been sent out, they had been met with the complaint that it failed to produce that distinct effect which was certainly obtained by sweet spirit of nitre made according to the old process.

The President said no one would dream of minimizing the work of Professor Leech, but that work was done from a chemical, physiological, and pathological point of view. But the practice of clinical research should not be lost sight of, and they should not be guided too much by theory in these matters. It was liable to express the result of experience. As a diaphoretic, no doubt the old-fashioned spirit of nitre was a different thing to ethyl nitrite, which affected the arterial pressure.

Mr. Ward said they were indebted to Mr. Jones for bringing this subject forward. It ought to be settled for the peace and comfort of pharmacists as well as for the satisfaction of the manufacturer. He had made a note as to the variability of ethyl nitrite. From a sample made on October 27, 1890, 1 C.C. gave 25 C.C. of gas. It was then put on one side, and was opened until December, 1890. The bottle was about three parts full, but there was no reason to suppose that a large amount of air had had access to it. When examined this 1 C.C. gave 7 C.C. of gas instead of 25 in 1890. He had examined it again this month, and found that 1 C.C. gave 4-5 C.C. of gas. It was made from as concentrated a solution of ethyl nitrite as was possible to obtain without having recourse to very special means, and was a fair indication of the liability to change which marked this body. It had been pretty well decided that the presence of moisture was to a very great extent the accelerating agent, and that if you had a sample of sweet spirit of nitre near which the liability to change was reduced. If pharmacists who did not make their own would insist on purchasing B.P. spirit of nitre instead of the 850, which was somewhat extensively purchased, they would insure a much greater permanence in the product. There did not appear to be much difference in the

The next paper read consisted of "Notes on the Geology, Botany, and River Systems of Oxford and Neighbourhood" by G.C. Bushe, M.A.

I have been asked to say a few words on the physiography of the country round our ancient and classic citie. I must ask those who know our district to pardon me touching on what they may be a thread-worn theme; and to those to whom it may be new and strange I must offer my regrets that this most interesting subject has not fallen into better hands to deal with. To all present an apology is needed for this innovation in our proceedings.

Situatted as we are, nearly in the centre of England, in the midst of fairly well cultivated and fertile country, we can boast no romantic scenery. We have no picturesque cliffs, mountain gorges, or picturesque waterfalls of Northern Britain or Wales. But although placed amid tamers scenery, our district offers to the visitor much to interest and charm. We can boast no great elevation of surface, but our highest point, Welbarrow Camp, south of Hungerford, is nearly 1,100 feet high, and the eminences in the northern part of Oxfordshire, such as Edgehill and Tewdon Camp, are about 800 feet. As late as the end of the seventeenth or beginning of the eighteenth century other ideas prevailed, for the then curators of Ashmole's Museum wrote to inquire of a few antiquarian which was the highest hill in Britain. Some, he says, "say Penygent, and others the Peak; but for his part he believes Stokenchurch Hill in Oxfordshire to be the highest in Britain." It was over this hill that the coach road from Oxford to London was made, and its greatest elevation does not attain 800 feet. Visitors, therefore, from our mountainous part of Britain must for the most part use the word elevation, or rather interpret it relatively to our more equalled surface, the factor in this lessened variability being the geological character of the rocks of which it is composed. The older primitive rocks of igneous origin, the Silurian or Cambrian, do not enter our boundaries. We belong to more recent times, and
our rocks—I use the term rather in the geologic than the ordinary sense—are stratified. The oldest formations are found in the northern part of the area, and are represented by the lias group.

From Banbury, travelling southwards through the district from Oxford to Reading and Windsor, the visitor will observe a succession of formations arranged in more or less regular bands, which cross the country almost west and east. These belong to successive periods of geologic history. With a trifling exception all the various strata in our area would thus be crossed in a railway journey of an hour and a half. In this succession a change in the rocks which causes the pleasant and varied character of the country which is passed through. But from the soft character of the formations, the variations are gentle, and the outlines of the scenery are marked by no abrupt changes or sharply defined forms. Instead we get gently undulating country, broad alluvial meadows, low and rather obscure escarpments, low tracts of arable land, gently swelling hills of chalk, and gravelly heathland as we pass along.

If, however, the visitor enters our boundary by the London and North Western Railway from Bletchley he does not cross, but, instead, will follow along one of these lower bands from west to east, and this formation is the London clay, which forms a low, flat, uninteresting tract of country. If our visitor comes from the west and enters Berkshire from Swindon, so, too, he will follow another band, in this case composed of gaults, which, like the Oxford; clay, forms low, flat, uninteresting country between Swindon and Didcot.

With your permission, therefore, I will shortly enumerate the various geologic formations found in our borders.

The oldest, as I have said, is the Lower lias clay, found in North Oxford, which exists as a blue, clayey material. Near Banbury it shows itself as a hard, shelly limestone, full of innumerable fossils, sufficiently dense to allow of its being worked into chimney pieces, which take a fair polish. It is locally called Banbury marble.

Next to this comes the marlstone, which forms an elevated plateau. This formation was once covered with the upper lias, but this has been denuded from the more elevated portions of its area. The top of the plateau is formed of a stratum called the rock band; it is a sandy limestone with a considerable percentage of shell: near Banbury it has been extensively quarried for iron ore. In 1874, 40,000 tons were quarried. Near Fawler, on the confines of Wychwood Forest, the same formation is also quarried for ironstone. One of our most local plants is found upon it, Thaspi perfoliatus, whose distribution is confined to three counties.

The upper lias consists of bluish clay and shales, which have been so denuded as now to consist only of narrow strips and outliers. A well-known pharmacist, Mr. Beasley, of Banbury, whose work in natural history has been so valuable, has made a very complete list of its fossils.

Lower quartes are represented by some sandy beds, which are found upon the Upper lias beds in North Oxfordshire. Epwell Hill, 743 feet high, is capped by them; as are also Wigginton, Crouch Hill, and Tadnorton.

The Northampton sand really includes two formations, one belonging to the inferior, the other, which is an upper portion, to the great oolite. Eastwards in Lincolnshire these formations are separated by a thick stratum of limestone, which has thinned out westwards, that in Oxford the two formations have met, and are almost indistinguishable.

**Great Oolite.**—To the south of the district covered the Northampton sands, the beds known as the Stonesfield slates occur in the form of a laminated limestone. This contains an immense number of fossils, not only of animals, but plants and insects. A very extensive series is preserved in the University Museum here. This stone splits readily along the bedding planes into slabs thin enough to be used for flooring. A patch of Wadham College may be cited as an example.

The Tainton quarries have produced the most durable stone in the country; Burford Church, Blenheim Palace, the inside of St. Paul's Cathedral, and many old buildings in Oxford have been built out of stone belonging to the great oolite.

The upper part of this formation consists of a group of limestone marls and clays. It forms a tabulated surface, intersected by narrow channel-like valleys. In fact, it forms a repetition of the marlstone plateau, and, like that, is dotted over with outliers, which in this case consists of Forest marble, capped by Cornbrash and Oxford clay. East of the Cherwell it is covered with a thick deposit of drift, which gives an undulating surface to the country near Brackley. The escarpment of the great oolite is much broken by faults. The interesting plants found on this formation are the very local: Botrychium, Pteridium aquilinum, Thalna perfoliata, Arragalis danica, Ophioglossum vulgatum, Cynoglossum montanum, Monotropa, the latter plant occurring on two small outliers, one at Islip, the other at Middleton. Plants which are especially abundant on this formation are Cimicifuga paniculata, Cardiium echinophorum, Brachypodium pinnatum, and Broom erectus.

The Forest marble is a sub-formation of the great oolite, and is so called from its occurrence in Wychwood Forest. It consists of hard, flaky, limestones, much ripple marked, and often formed of oyster shells cemented together by carbonate of lime. It is rarely irregular in form, being generally more in the cornbrash, which is the upper formation of the Lower oolite, and consists of a group of limestones, very regular in its bedding, and which stretches across Oxfordshire in a rather regular band of not very interesting country. It is well adapted to the growth of wheat. A curious row of small daughters of the cornbrash are brought up along an antecedent line stretching far eastwards. They occur as dome-shaped masses, rising out of the flat, dull plain of the Oxford clay, and on these intervals many villages have been built.

None of the foregoing formations extend into Berkshire.

The Middle oolites consist of the Oxford clay, the lower calcareous grit and coral rag. The former I have alluded to; it consists of a thick blue clay, weathering on the surface to yellow. It covers a broad tract of country from Lechside, by Bampton, Durley, and Wantage, the dreary flat of Otmoor eastwards, to the Bucks border. It is to this formation and the proximity of the river that Oxford owes its humid and relaxing air. The Oxford clay is 600 feet thick near this city. In the west a thick deposit of drift occurs, the Wychwood outcrops being overlain with a quartzose gravel at an elevation of 500 feet. On these places several ericetial and uliginal plants occur of interest, such as Erytrhea pulchella, Sagina nodosa, Scirpus fluviatilis, Pilea, Comarum palustre, Mentha piperita, M. sylvatica, Stellaria palustris, and Rumex maritimus. One very rare and exceptionally interesting plant, occurring in the Oxford clay, is Scirpoid palustris. Roses are very variable on the clay, while Rubi are but poorly represented. The lower calcareous grit and coral rag form an elevated plateau overlooking the Oxford clay, which extends from Faringdon, by Cumnor, immortalized by Scott, to Beckley and Stanton. Although this plateau is of no great height, yet very extensive and beautiful views
may be obtained from the top of the northern escarpment. *Arabis perfoliata, Viola tricolor, Sedum dasyphyllum, Corum setosum, Calamitha nepeta, C. monotropis, Geranium rotundifolium, G. pyremitum, Erysimum sp., Carduus tenuiflorus, Impatiens parviflora, Armeria maritima, and many other plants occur.* The softer forms are formed by streams which flow from its escarpments afford the most interesting bog land in the district. The list of plants is too extensive to give in anything like detail, but I may say that *Scirpus sylvaticus, Potamogeton plantagineus,* three species of Urticularia, *Parnassia, Pinguicula, Drosera,* and *Dentaria* occur. The softer forms of sedges are also very frayed.

The Headington quarries in this formation have yielded much of the stone of which Oxford has been built. The ruined condition of many of the walls is owing to the use of this stone, which weathers very badly, especially if it be put in so that the bedding planes are exposed. The bridge at Henley is also built of this stone. It is largely composed of shells and corals.

We now arrive at the upper colliette, represented by the Kimmeridge clay and the Portland sand and Portland stone.

The Kimmeridge clay is a very stiff, dark blue, or olive green clay, sometimes sandy, and occasionally with bands of fossiliferous limestone. It stretches in an irregular band across the country, often forming flat pasture land, but on the eastern side is obscured with a thick deposit of drift. Large crystals of selenite are found in it on Shotover Hill. In Berkshire, at the juncture of it with the overlying colliette, one of the springs which it throws out is sufficiently saline to give rise to a partly marine flora. *Scirpus maritimus, Aegium graecisum, Carex distans,* Sparganium marina, Laminnicia pedicellata, Vanhorchia dichotoma, var. semialata, etc., occur.

The Portland stone preserves the calcareous grit. They are found on the Shotover range. The Portland stone is a white limestone, which, like the Portland sand, is only very sparingly represented in the area. The higher portion of Shotover Hill is formed of these beds. On the ordnance map the iron sands on the top of Shotover Hill are coloured, as if they belonged to the lower greensand, but they have also been placed in the Purbeck beds; now they are believed to belong to the Wealden series, a fresh water formation. These sands contain a very thin bed of excellent ochre. The vegetation on them is also very thin. The moulds have done much to rob it of their characteristic flora.

The cretaceous formation next claims attention. The lower greensand makes a light arable soil. At Farlington it forms the well-known sponge gravels. For a considerable distance in the Vale of Berks this band of lower greensand is overlapped by the gault. The hills of Foxcombe, Boars Hill, the pleasant wooded district of Nuneham (which we shall see on our excursion), are of this formation.

The gault, which is a pale blue clay, extends in an unbroken band across the area, the ground is flat and often marshy. *Rhamnus maritimus, Fruticaria, Sides cernua, etc., are found on it.*

The upper greensand extends parallel with the gault in a belt of valuable arable land from Wiltsire to Buckinghamshire.

Next to this comes the chalk, which forms an ele-

may be distinguished by the occurrence in the upper chalk of flints, which are usually placed in the bedding planes. The cutting at Pangbourne shows this very well indeed. The flora of this district is peculiarly interesting—*Orchis militaris, Ophryopus muscaria, O. muscaria, Nottia, Linaria repens,* *Iberis, Helleborus obovatus,* and many other plants occur. The southern aspect of the escarpments are made annually. It is prepared from the upper chalk by a rough process of grinding and attrition. The chalk country of Oxford forms a portion of the Chiltern Hundreds. In the south part of Oxfordshire and the central part of Berks the chalk becomes more or less covered with tertiary deposits. Between them and the deposit of the chalk formation, which you know, is to a great extent composed of Formanitium (which our revered member, H. B. Brady, studied so closely), an immense interval of time elapsed, the interveining beds either having been denuded off, or the chalk itself having been buried. These tertiary beds belong to the Eocene formation, and consist of the Reading beds, and London clay. It is to the occurrence of these two formations that the healthy character of so large a portion of the south is due. The Reading beds consist of alternations of clay and sand. The London clay sometimes contains septaria. Near Westcote it reaches an elevation of about 500 feet. On these formations such plants as Centunculus, Raddia, Brassica hirta, E. cinerea, and Vaccinium are found. To the Eocene series may be also placed the Bagshot beds, which cover a large surface of southern Berkshire, but which do not extend into Oxfordshire. These Bagshot beds, gravel, with occasional seams of pipe-clay. The surface of the country on them is completely changed, heath-land, pine plantations, and hilly country, with deep alder gullies, and bogs covered with sedges, cotton grass and bog myrtle are to be found. So interesting plants of this area are Luneaorhis, *Hy-"
From this point to the Nore the river measures 210 miles. For 110 of its course it touches the counties of Oxford and Berkshire, and the bridge over the Thames near Lechlade—where was formerly a priory of Black Canons—to Old Windsor. From Lechlade to Oxford its bed is principally excavated in Oxford clay, the escarpment of the coralline oolite overtopping it on its southern side, while the Faringdon Clumps, planted by the poet Pope, are within the limits of Wiltshire, and the first-topped Hirst of Cumnor, so often aluded to by Matthew Arnold, are prominent objects on its southern side.

In its progress through our district the Thames receives many tributaries. Among these may be mentioned the Windrush, which, like the Thames, takes its rise from the Cotswolds, and is the largest affluent of the Thames. Drayton called it the nitrous Windrush. In its rather straight course through Oxfordshire it passes by Burford, which has in its midst a magnificent church, and through a country which was, at the beginning of the century, open downs, covered with short sweet grass and redolent of thyme, where *Anemone pulsatilla*, the musk orchis, the field frag-wort, the purple milkweed, and the spider orchis grew, but which now, alas, are bleak tracts of arable land, with only occasional strip of grass by the road-side to tell of the former vegetation. In such places *Stachys germanica* is still to be found. Passing Witney, whose ancient industry of blanket manufacturing was fostered by its water, the Windrush enters the Thames near Cokethorpe.

The Evenlode, another tributary, brings in its turbid waters gathered at its commencement from a wide tract of fens, which forms an obscure and low, and not very recognisable watered space between the Thames and Severn, about 450 feet above the sea between the “town of Blow and loomb.” The Evenlode runs its course of 30 miles in winding streams, whose general direction is almost parallel to that of the straighter stream of the Windrush. It passes by Cherhill, the birthplace of Warren Hastings and Wm. Smith, the father of geological science, and, washing the ruined Augustinian monastery of Bruern Abbey, glides under the bridge and slips of Woodstock, and in its course by Stonesfield quarter, has its waters gathered through well-wooded and picturesque country, forming part of the demesne of historic Woodstock, itself lending a great charm to the scene by its beautiful curvatures, bordered by terraced slopes, whose tufted tops are there and there adorned with the pencilled flower of the wood-vetch, or starred with the rare rose. Wychwood contains two species of *Daphne mezereum*, *Atrpeta belladonna* in plenty, and both *Ficaria verna* and *viridissima*. The curious toothwort, *Lathraea*, is also found there, as well as the rare *Lathraea fissa* and the limestone poppy. The Evenlode, together with the Thames, is Castledown, once the home of the Percys of Northumberland. From this spot the Thames curves in a bold sweep to the northwards, round the beautiful woods of Wytham. These woods are situated on the sides of an eminence, once the site of a castle belonging to Cynwulf, King of the West Saxons, commanding extensive views of the sea of the Upper Thames. They are very interesting from a botanical point of view, containing as they do *Atrpeta, Hyoscyamus, Verbascum thapsus, Daphne mezereum, Samolus, Astragalus glycyphyllus, Monotropa, White flowered helleborine, the bee, the frog, the newt, and buttercup orchis, Orchis pumila*. Near Wytham is Godstow, where *Aristolochia petiolaris*, and the rare *Nolitella macrona* has been seen. If Yarnton the Thames turns southwards to Nettlebed, where the maximum amount of water passing in flood time was estimated at over 70,000 cubic feet per minute. At a short distance from the farm by Olney, near Woodstock, which has a catchment basin almost equal to the Thames above Oxford, namely, 600 square miles. It rises in Hampshire, near Charwelton, on the elevated table land of the Vale of the White Horse, which is excavated for the most part in Kimmeridge clay. In this area *Doronicum pardalianches, Polygonum rubrum, Sedum spathulifolium, Calamintha nepeta, Wahlenbergia hederacea, Vicia paludalis, Equisetum sylvaticum* occur. Below Abingdon the Thames soon passes into oystaceous beds, and at Clifton Hampden flows past bold cliffs of conglomerate, formed by the green sand, to Dorchester, which is on the site of the ancient camp, Dorum Hancium, a very early British settlement, and which gave its name to the episcopal see founded by Birinus in 634. Under the walls of the magnificent church flows the Thames, which rises in the high ground of Quanton and Brill, and the lower chalk escarpment near Tring, in Buckinghamshire, drains in its former course a very similar tract of country to that drained by the Ock in Berkshire. The river near Dorchester affords the beautiful Snowflacke, and it is bordered by *Acorus calamus*, which I believe to be native by the Thames.

From historic Wallingford the Thames continues its southern course through a narrow and beautiful green valley adorned with fine elms and bordered by hedges of chalk often well wooded on the slopes, or studded with bushes of Juniper. These woods have belladonna, Solomon's seal, the butcher's broom, the monkey, soldier, bee, fly, frog, burnet, bird's-nest, and many other orchids, *Pyrola, Lily*, many slopes are replanted with the chalk milkwort and horsehoe vetch, or here and there show *Anemone Pulsatilla*, *Lactuca virosa*, which is to be seen on the wooded banks, and in the more inland portions *Daphne mezereum* is native. In the course from Wallingford to Reading the Thames receives a small Berkshire stream called the Pang, so called from a Saxon word signifying pain on account of the hardness of the waters. From lovely Pangbourne, beloved by artists, where the bright but calcareous water of the Pang mingleth with the greener coloured Thames, the parent stream passes on under the hanging woods of Whiteclerk and, by Mapledurham, the hearse-man's mill, and by the Elizabethan mansion of the Blounts to the busy town of Reading. A locality for *Galium sylvaticum* is in this vicinity. At Reading another feeder of the Thames comes in, namely, the Kennet, bright for silver eels renowned, whose principal source is in the chalk downs of Wiltshire, but which has also two Berkshire tributaries, the Lambourne and the Emborne. The one rising near the seat of Alfred, and the ancient battlefield of Glastonbury, the other passes from High Cleeve, by the site of Falkland's last battle. In this area the bog myrtle, *Rhacena frangula*, of the mires, two *Urticaria*, and many other interesting plants are to be found.

From Reading the Thames passes by the hanging woods of Sonning, with *Dipsacus pilosus, Scirpus sylvaticus*, and passes under Shiplake's ancient bridge, near which grows the great dodder, and then receives
the River Loddon, which Pope described as the "Loddon slow with verdant alders crowned," a stream of great charm, and extremely rich in vegetation. It is the home of the rare Petasitogona fistulosa, P. rupestris, Typha angustifolia, Carex stricta, C. acutifolia, C. vesicaria, etc., and a profuse growth of the lovely Snowflake. From Shiplake the Thames passes Henley, the most ancient town in Oxfordshire, and Park Place, situated on high ground 300 feet above the river. Linaria repens is plentiful here, as Hypericum monotonum, Euphorbia, Eruca, Dianthus armeria, Spiranthus aurantiacus, and Viscum are also in the vicinity. Between Hambledon and Marlow is "that beautiful valley through which the Thames, not yet defiled by the precincts of a great capital, nor rising and falling with the flow and ebb of the tide, rolls under woods of beech round the gentle hills of Berkshire."

I may now just allude to the fact that the ancient culture of wood was carried on at Wantage until the beginning of this century, and that in a village near Didcot a small quantity of hope has been grown for many years.

The following plants found in our area are of especial interest to the pharmacist:—

The President said they could not expect the Conference to discuss this paper in the ordinary way, but he was sure they would be all ready to get up and express their thanks to Mr. Druce for the marvellous view he had given of so wide a subject. This paper had formed a most interesting discourse to other papers, and it occurred to him that, as in connection with the British Association there were evening lectures which formed a great feature of their meetings, so it might be possible at future meetings to devote the Tuesday evening of the Conference to any special feature connected with the district in which they were assembled, where there was a man capable of dealing with any of the special features connected with the natural science of the neighbourhood, though he did not suppose they would always be able to find so capable a man as Mr. Druce. It was truly marvellous that he should be able to say so much in so short a time.

(To be continued).

Books, etc., received.

Dispensing Memoranda.

[657.] A correspondent sends the following prescription, in dispensing which an energetic reaction took place, CO₂ being evolved, and a certain amount of CaCO₃ formed, whilst other decompositions, concerning which information is desired, seemed to be proceeding at the same time:

Notes and Queries.*

LIN. SAPONIS.

[767.] It is suggested by F. Hemm that the best way to prepare this liniment is to digest the soap, fine powder rather than in shavings, with water until a translucent jelly results, then dissolve it in the alcoholic solution of camphor and oil of rosemary—(Am. Journ. Pharm.).

Softening Hard Extracts.

[768.] Referring to England's recommendation of glycerin for softening extracts, prior to making doses from them (see note 756 on page 69), a correspondent states that glycerin, though excellent in many cases as a solvent, is not to be recommended in this particular instance; owing to the oleaginous character of the glycerin, the hard extract constantly eludes its action, whether the softening process is attempted by means of pestle and mortar or on the pill-slab. When hard extract has to be incorporated into a suppository, a few drops of spirit will render it to a fit consistence, a plan to which there is no objection, as the spirit is entirely evaporated long before the suppository is finished. Supposing the hard extract is not intended to be mixed with either fat or oil, a few drops of boiling water will suffice to make the extract plastic, after which a minute quantity of glycerin should be added to ensure its preservation.

Phosphorus Pills.

[789.] Three methods of dispensing phosphorus pills are described in the Journ. de Pharm. d'Amèr. (Vol. xxxi., 500 Gm., on a water-bath, add phosphorus, 1 Gm., and heat until melted. Then pour the mixture into a mortar and stir until cold. (2) Mix intimately red phosphorus, 1 Gm., with starch, 50 Gm., and an exfoliant very fresh curds, employing a wood mortar for the operation. Dust the pills with starch and preserve them in tin boxes. (3) Dissolve

* For the sake of ready reference it is convenient that the notes and queries should be numbered, and it is thought desirable that the numbers should be correlated with those that have appeared in former volumes of the Journal (see Vol. xiii., p. 596). The first note on p. of the present volume should therefore be numbered 747, and subsequent ones accordingly.
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS.

CRESOCE PILLs.

[790] New methods are continually being proposed for these pills and old ones being revived in different medicinal journals. Thus, A. Stern forms a mass containing cresote, 5 parts, and balsam of tolu, 12 parts. The balsam is half melted in a porcelain capsule as a gentle heat, the cresote added to be semi-fluid, and the mixture stirred with a glass rod. Whilst yet warm the mass is run on to a marble slab and left to cool, after which it is preserved in a well-closed vessel until required. When about to make pills, powdered balsam of tolu, 12 parts, is mixed with cresote, 5 parts, and 17 parts of the above mass added. No other excipient is required; the form of the ointment masks that of the cresote; and, if uncoated, the pills may be kept for a considerable length of time. Other medicaments may, of course, be added, and should be first mixed with the powdered balsam of tolu. E. Dieterich triturates calcined magnesia, 1 part, with glycerin, 2 parts, then gradually the cresote, 10 parts. Calcined magnesia, 5 parts, powdered extract of liquorice, 5 parts, and sugar powder, q.s., are then added in the order named. The pills should be dusted with finely powdered coffee, or with a mixture of coffee and cinnamon.

They may be dispensed in the same way. W. Kollo disperses the cresote with two drops of water to each gramme, any soluble medicaments required being triturated with the water. Extract of liquorice very fine powder (poudre tres fine du soc de masse) is then added until a soft mass is formed, from which insoluble substances such as quinine may be added, and the desired consistency obtained. The addition of powdered liquorice root, q.s., on a small scale, and eucalyptol may be mixed in the same way, but instead of water syrup should be added, and its weight in the medicament, and whilst finally triturating in a mortar a little gum arabic as much powdered extract of liquorice as necessary should be added. The soft mass formed is moulded as before, except that a little magnesium carbonate should be added. The medicament will contain 25 per cent. of the finished mass. The pills proposed for the supplement to the German pharmacopoeia is cresote, 10 Gm., liquorice powder, 8 Gm., glycerin, 1 Gm. Make 200 pills and roll in powdered cinnamon. Each will weigh 0.16 Gm. and is 0.05 Gm. of cresote (Mon. de la Pharm).

ANTIMONIUM TARTRATUM, B.P.

[71] "Will you inform me if the B.P. is correct in saying, under tests for antimony tartrate, that 29 grams of antimony in water, and H₂S passed through, yield a test which when dried weighs 15½ grams? I can make it come to 14½ grams.—R. H. MARSHALL.

Antimonium tartratum, B.P., appears to yield more than the theoretical proportion of sulphide, because the precipitate is liable to contain moisture, oxygen, free sulphur, and solid tartrate of potassium. According to Watt's 'Dictionary of Chemistry' the orange-red precipitate is amorphous hydrated Sb₂O₅, which is only fully dehydrated at 200° C, whereas in the B.P. process the temperature of 100° C. is adopted for dehydration. The abandonment of determination by sulphide and the substitution of Mohr's volumetric method were recommended by Professor Atfield, in his report on the pharmacopoeia for 1888.

Correspondence.

THE PREPARATION OF SUPERFATTED SOAP, ETC.

Sir,—The answers to Mr. Moffat's criticisms on my note upon the preparation of superfatted soap, etc., are obvious and easy. Undoubtedly, the sample of caustic potash I used in my former communication I one. This accounts for the seemingly large quantity of the alkali required for the complete neutralisation of the lard. Unfortunately, I have none of that particular potash left, so that I am unable to determine its strength. It was not therefore an old stock. I have estimated seven samples of KHO, taken at random, and found a very considerable variation in their strengths.

The figures are—

<table>
<thead>
<tr>
<th>Sample</th>
<th>Strength of KHO in per cent.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>60.6</td>
</tr>
<tr>
<td>2</td>
<td>28.8</td>
</tr>
<tr>
<td>3</td>
<td>28.4</td>
</tr>
<tr>
<td>4</td>
<td>29.2</td>
</tr>
<tr>
<td>5</td>
<td>29.7</td>
</tr>
<tr>
<td>6</td>
<td>73.3</td>
</tr>
</tbody>
</table>

It will easily be seen that it is manifestly unfair of Mr. Moffat to condemn my figures, based upon work done with a weaker alkali than the one used by himself, or to find fault with my figures at all, since he cannot possibly know the strength of the KHO used by me. It is impossible, in the face of such variation in the strength of caustic potash, to pretend to give any definite formula for such a preparation as the one I allude to. I do not do so. I suggested the calomel test because it is a simple and easy one, and in the hands of the ordinary pharmacist does away with the troublesome and tedious method by titration. Very few pharmacists even keep stock solutions at hand, and of those who do, how many use vol. sol. of HCl? I claimed for the calomel test that it held to one-tenth of a gram, when working with over 800 grams of the soap. Mr. Moffat does not dispute this, but states that "it failed to indicate the presence of very appreciable quantities of free alkali, which were immediately detected when the alcoholic solution of the soap was tested with phenol-phthalein." I adhere to my former statement of the value and usefulness of calomel as a test for neutrality. I have since compared the tests many times, and have found the phenol-phthalein bear out the calomel test in every instance, although in the case of hard soaps an alcoholic solution was not always so readily obtained, and the application of the calomel test was a great saving of time. In no case in my hands has the calomel test failed where the phenol-phthalein has also indicated excess of alkali. I see, therefore, no reason to alter the recommendation I made first. I distinctly stated that the figures given were only those obtained from samples of KHO and lard then at my disposal. With the calomel test the pharmacist can rapidly and accurately know when he has arrived at neutrality in the preparation of the soap. If there is one point I would suggest, it is that the lard and KHO should be given rather more time to combine, since when working with large quantities three or four days seems hardly sufficient.

The Royal Infirmary, Liverpool.

J. R. JOHNSON.
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS.

The Nostrum Trade.

Sir.—Your leader in the Pharmaceutical Journal of July 28, and Mr. Martin’s address at Oxford bearing so strongly upon the same subject, are worthy of the most serious consideration by the whole body of registered chemists and druggists. You say the druggist should cease to sell quack nostrums. Mr. Martin says the time is very near when pharmacy must make its choice between trade and prescription. The druggist who nan be prepared to take place in English pharmacy, or even that the trade element should form the smaller portion, is to many of us quite utopian. There are among us many who willingly wash their hands of every thing, but the difficulty is to know where to draw the line between clean and unclean, and we cry to you and the leaders in our craft for “light,” “to lighten our darkness.” Had the chemists and druggists of the past gathered and more rapid competencies than their neighbours we might infer that the large profits on drugs had been abnormal, and that the raids made upon our preserves by outsiders were somewhat justified; but history has recorded nothing of the kind, and experience and custom have alloted to each calling a tariff of remuneration fairly just and equal. Even if the Pharmacy Act were passed, as it is said, for the benefit of the public, philanthropy is still not the first cause of its promulgation. Could you suggest that he take his stand on the fairly distinct principle that he supplies nothing but what he has either made himself, or the composition of which is stated on the pharmacopoeia? Even when the advance is not much, for the retailing of the purest drugs is trading; and in sponges, invalids’ foods, surgical and sanitary appliances, &c hoc genus (which, I think, all will admit most naturally to the domain of the pharmacist—vablye redi sanitatis), we have a large trade element to deal with; indeed, so large is the field that, considering the rapid and apparently successful extension of the company chemist’s business, the very serious question arises whether it would not be wise to treat trade matters on trade principles, extending them to their utmost rather than giving them up altogether. After thirty years’ experience behind the counter I fail to see the slightest increased tendency in medical men to cease compounding their own medicines. If we give up the trade, what is there left? In the words of the song the chemist might then truly say “He don’t know where he’s at.” Can nothing be officially done about a more rapid advance in this matter, and to induce the general practitioner to treat the pharmacist with greater liberality? The outlook is strained and perplexing to those anxious to uphold the dignity of the profession, and at the same time procure bread and cheese for themselves and families.

Upper Tooting, S.W.

Jno. Ingham.

The Revision of the British Pharmacopoeia.

Sir,—I now submit some further notes, in continuation of those already sent, at page 1105 of last volume. —

Ung. Acid. Bor.—This seems to be the only ointment of the B.P. in which, from a pharmaceutical point of view, it is desirable to retain the paraffin base. By following out strictly the directions given in the text, and adopting all reasonable minuteness which practice readily supplies, we may obtain in all respects a most satisfactory preparation.

Ung. Acid. Carb.—Here the formula does not at all answer. The acid gradually cesse out centrifugally and collects at the bottom; leaving the upper surface, left to the natural mode of appearance, most readily so when ordinary carbo acid is used, and eventually after about a month, when the purest kind of paraffin is employed. After repeated experiments the following combination seems the best that can be devised:

Take of—

Pure phenol 2 parts

English beeswax 3

Spermaster 3

Best olive oil 12

Melt together with the smallest possible amount of heat, adding the phenol last, had constantly until cold. Of this I have on hand a sample of stock prepared in January last, as well as some prepared in April; both are still uniformly in perfectly good condition.

Ung. Balsam.—It seems best in this to replace the paraffin by good English beeswax.

Ung. Hyd. Nit. Dil.—Prepare this with pure let place of the soft paraffin.

Ung. Hyd. Ox. Rub.—Why not restore the formule B.P. 1867, which really leaves nothing to be desired, in place of—

Red oxide of mercury, in fine powder... 63 grains

English beeswax ... 24 cones

English drawn almond oil... 6

Melt together in the double boiler, and add the oxide when congealation is just about to take place.

Ung. Resina.—Simplify thus:

Take of—

English beeswax ... 6 cones

English drawn almond oil... 8

Amber resin, in powder ... 6

Pure lard ... 6

Melt together in the double boiler, and add powdered resin over the surface of the heated mixture until dissolved, then remove from the source of heat still diligently until cold.

In conclusion, I would like to add that the open trade seems to be an advantage for a great trouble that has crept into modern pharmacy. Not so this with regard to honey, wax, and the thousand more one simplifications of almond and olive oils. Now, I have a doubt that, even in the pharmacopoeia of any country, not alone for the encouragement of native industry, but more because of comparative ease with which the genuineness of such things is determined in contrast with the difficulty of diagnosis in the case of foreign products, and the plenitude of tracing simplifications home to the guilty. The cheapness of the paraffins, too, is an unskill in the unfair displacement of the far worthier yard. I am satisfied that perfectly pure lard will much better and longer than paraffinum mollis, it becomes and that the item in the same manner which such as fresh and fresh. More commonly the unsuitable character of the vessels in which they are stored, or the effect of the temperature of the locality is, at fault, and remedied by proper attention to reasonable detail.

West Marylebone.

J. C. H.

Emplastrum Vesta, P.B.

SIR,—I should feel obliged if your readers would suggest a remedy for the variability of this plaster, I have had repeated complaints that it does not adhere to after several applications. Samples used have been tried on various horses; and since the plaster is known to fail so often, I would like to bring this fact notice for its improvement.

West Brighton.

Answers to Correspondents, &c.

D. Dickinson.—Polytrichium commune. 2. Obtusum. 3. Sphagnum acutifolium. "P. G."—1. Probably a wild plant. Send a plant with lower leaves. 2. Verbena officinalis. "Secundinum."—You appear to have sent the second and third of your holiday collection to be named, overlooking the first and third with the name of a couple. I can identify them all for yourself. Whilst always willing to afford any reasonable amount of assistance, we cannot always occupy time and space by doing and recording would be of any real value, students should do their best. The more interesting specimens are duly named, but do not send more than six at once, in future. 3. Millefolium. 5. Prunella vulgaris. 7. Epimedium. 8. Spiculae Kirkianae. 11. Dioscorea delavayi. 12. Cyrtisus scorpius. 26. Truncum scorpius. 34. Potentilla tormentil. 41. Papaver.

Correction.—On page 141, column 1, line 20, for phlgeias read Magnoliceae, namely Drisys.

Communications, Letters, &c., received from Elborn, Hill, Lunn, Martin, Naylor, Parker.
Osborne and Voorhees have separated from the wheat kernel five distinct proteins—gliadin, glutenin, a globulin, an albumin, and a proteose, besides a proteose-like body. Gliadin is readily dissolved from wheat flour (4.3 per cent.) and from gluten by hot dilute alcohol. It also exists in the rye kernel, but is quite distinct from the alcohol-soluble proteins of barley, maize, and oats. When dehydrated it forms a snow-white, friable mass, easily reduced to powder. If dried after moistening with dilute alcohol or water it resembles pure gelatin in appearance, and may be obtained in thin, clear, transparent sheets. It becomes sticky and highly dissolves when treated with cold distilled water. As the temperature of the water is raised, the amount dissolved is proportionately increased, but the solutions deposit partly on cooling, precipitation being instantaneous on the addition of alcohol. Gliadin is entirely insoluble in absolute alcohol, and gives the usual protein reactions with Millon's reagent, with nitric acid, and with the biuret test. A beautiful violet colour develops on dissolving it in concentrated hydrochloric acid, and a similar colour with warm dilute perchloric acid. On boiling in aqueous solutions, gliadin coagulates and becomes insoluble in alcohol and in 0.2 per cent. hydrochloric acid but is dissolved by a 0.1 per cent. solution. glutenin (3.9 per cent.) is very similar in constitution to gliadin, and might be regarded as an altered and insoluble form of it. There is no evidence that the latter is actually transformed into glutenin, and the two substances are probably quite distinct. Edestin, the globulin, belongs to the vegetable vitellins. It is soluble in nine solutions, from which it is precipitated in dilution, or by saturating with magnesium ammonium sulphate, but is not precipitated in saturation with sodium chloride. The wheat kernel contains about 0.65 per cent. of edestin. Like gliadin it is albumin, forming about 35 per cent. of the wheat kernel. It coagulates at 65°, and is unlike animal albumin in being precipitated by saturating its solutions with sodium chloride or magnesium sulphate. The proteose present occurs to the extent of 0.3 per cent., and the amount of the proteose-like body was roughly estimated at 0.2 to 0.4 per cent. Both gliadin and glutenin appear to be necessary for the nutrition of gluten, but these substances alone are not sufficient, and no ferment action seems to be involved in the process. (Journ. Am. Chem. Soc., 54, 636.)

Blatchyrophyllates. C. Friedel has been able to prepare compounds of sulphuric phosphorus, belonging to a new series, the type of which corresponds to the salts of hypophosphoric acid. Iron hypophosphosphate, Fe₃P₂O₈, occurs in light-black hexagonal plates resembling graphite; the copper salt, Cu₃P₂O₈, forms small cubes; aluminium and zinc yield white and pale brown compounds respectively; whilst the thio-phosphates of lead, silver, mercury, and tin have also been obtained and are duly described in a paper (Compt. rend., cxvii., 260).

In a paper read before the British Association, Wanklyn and Cooper announced that the results of a lengthy investigation conducted by them indicate that the atomic weight of carbon should be taken as 6 and not 12, as commonly supposed. A number of hydrocarbons existing in commercial Russian kerosene would require, with the present notation, to have their formulae written with fractions, whereas, regarding the quantity of carbon in the standard volume as a multiple of 6, this difficulty at once disappears. In an additional note in the Chemical News, J. A. Wanklyn states that, according to his view, carbon is tristominic, all the compounds conformational with the ordinary theory being thus embraced, in addition to carbonic oxide, the case of which is difficult of explanation "by chemists who write carbon with an atomicity of 4 and an atomic weight of 12." According to Wanklyn, carbonic oxide is quite regular, being the analogue of nitrous oxide, thus:

\[
\begin{align*}
\text{Carbonic Oxide} & : & \text{Nitrous Oxide} \\
\text{C} & > & \text{O} \\
\text{C} & > & \text{N} \\
\end{align*}
\]

In the discussion which followed the reading of the paper at Oxford, Professor Odling seemed to express the views of the meeting by stating that the evidence offered was too slender for chemists to give up well-established conclusions and be convinced that the atomic weight of carbon was 6 rather than 12. The determination as 12 was based on such a mass of converging evidence that it would require a very great deal to upset it, and much more than the boiling points and vapour densities of the new hydrocarbons must be known before arriving at a conclusion of such importance.

Living and Dewar have conducted experiments with a view to observing the occurrence of atomic spectra in the discharge of electric air and nitrogen, when stimulated by the electric discharge, at temperatures of 160°-200° below zero. Platinum electrodes were employed, and in the case of oxygen the spectrum was chiefly a continuous one, brightest in the yellowish-green, but extending for some distance both on the red and blue sides. The absorption bands were conspicuous on this bright background. Much ozone was formed during the passage of the discharge, and imparted its characteristic indigo tint to the liquid. With liquid air the effects were similar, but oxides of nitrogen were produced, and liquid nitrogen gave a continuous spectrum with three bright lines in the green and yellowish-green, generally resembling those seen in liquid oxygen. For the sake of comparison the spectrum of the spark in distilled water was observed. This was also continuous, with the red line (C) of hydrogen conspicuous, and the F line just visible, and glimpses of the three platinum lines in the green and yellowish-green. The bright lines seen in all cases were traceable to the electrodes, and it seems not unlikely that the continuous spectrum was due to particles thrown off from them (Phil. Mag., xxxviii., 233).
T. Marie describes a method for the extraction of the free acids in beeswax, which gives good results if it is applied to mixtures of acids, so long as bodies both hydrocarbonic and organic are absent. Beeswax, when treated by boiling alcohol, yields to this solvent not only the free acids present, but also hydrocarbons, oleic compounds, colouring matters, and myrrhin, which are difficult to separate properly. The method adopted for obtaining the acids free from these other substances is as follows:—After the wax has been treated by the boiling alcohol, the greater part of the latter is subsequently distilled. The cooled and crystalline residue is then squeezed to separate oleic compounds and colouring matters, after which the solid cake is melted, washed repeatedly with boiling water, and further decolorised by charcoal and filtration through paper. The slightly yellow mass thus obtained melts at 70°. This, after being heated with potash and lime, is cooled, powdered, and mixed with a large quantity of water, which is then heated to沸腾. Dilute hydrochloric acid is then added to neutralise the alkali, and the free acids of the wax combine with the soluble calcium salts in the mixture to form insoluble compounds. The latter are separated, washed, and dried, then treated with boiling alcohol and benzene to remove neutral substances, and decomposed. The acids thus isolated, after crystallisation from alcohol, which removes a small quantity of palmitic acid formed from the myrrhin, melt at 75°-80°. By further treatment, with methyl alcohol, ceric acid is dissolved out, and on crystallising is found to melt at 76°, the melting point being raised to 77°-5 after a single crystallisation from ethyl alcohol. The residue melts at 78°, and contains melissic acid, described as identical with that extracted from carnauba wax by Story-Maskelyne and Pievier. Crude ceric acid is said to contain from 30 to 40 per cent. of analogous acids, and Marie announces his intention of further studying the pure compound and its derivatives (Comp. rend., cxiv., 428).

This is a compound obtained by C. Friedel, which has the same composition as caphonic acid—C₃₅H₇₃O₂.

It is found in the residue left on preparing the latter, and is a colourless oily liquid with a disagreeable odour, recalling that of valerianic acid. It boils at 180°-181°, has a density at 0° of 0.9941, and its rotary power is [α]₀⁺⁺ = +24° 38′. The acid is almost insoluble in water, but it mixes with alcohol and ether, and its salts crystallise readily from any of these liquids (Comp. rend., cxiv., 278).

Barbier and Bouveault assert that Bertram and Gildemeister are wrong in concluding that the lemonol of Anadropogon schenanus, the alcohol of essence of pelargonium, and the rhodinol of ote of rose are identical to the alcohol provisionally termed the rhodinol of pelargonium possesses a strong odour of roses, has a density of 0.8866, and is associated with another compound, greatly resembling licareol. Altogether, it is found that the essence of pelargonium contains six different substances, the rhodinol-like alcohol predominating. The constitution of this alcohol is considered in a subsequent paper by the same authors (Comp. rend., cxiv., 281 and 337).

Sensitive Copper Reaction. P. Sabatier, whilst experimenting with the bromide and other compounds of copper, noted that a very intense coloration was produced on dissolving a little of the bromide of concentrated hydrobromic acid. The colour is due to the formation of a purple hydrous compound, and he bases its formation a very sensitive test for copper salts, since it is quite appreciable when a single drop of an aqueous solution of a copper salt, containing one part of copper in 30,000, is added to a cubic centimetre of colourless, concentrated hydrobromic acid. The delicacy of the reaction is somewhat impaired by the presence of free bromine, the colour of which makes the lilac tint, but on heating the liquid to ebullition the latter becomes apparent and the bromine is driven off. If desired the concentrated hydrobromic acid may be replaced by potassium bromide in a saturated solution of orthophosphoric acid. On adding a drop of a copper solution to this, heating to 100°, and then cooling, the coloration is distinctly visible, its intensity depending on the proportion of copper present (Bull. de la Soc. Chim. de Paris, [3], xi., 683).

Iodides and Mercury. Berthelot refers to the two isomeric forms of iodide of mercury—red and yellow. Yellow is the more stable at the temperature at which the vapour is condensed. On cooling to the ordinary temperature becomes so unstable that contact with the red isomer is sufficient to determine the transformation of the yellow into the red compound (Bull. et Mem. Chim. de Paris, [3], xi., 748).

Citrific Acid in Milk. L. Vaudin shows that citric acid exists in cows' milk in the form of alkaline citrate, which serves to keep in solution the calcium phosphate, that the alkaline citrates and phosphates and cium phosphate are present in the liquid in proportions which are relatively definite. Cow's milk contains from 1 to 1.5 Gm. of citric acid, and it is exhausted by the calf's milk from 60 to 60 Gm. per cent. Vaudin is of opinion that the acid is formed in the mammary gland at the expense of the casein, that the citrogenic function of the gland, varying in different species, assures the partial solubility of the calcium phosphate contained in the milk (J. de l'inst. Pasteur, viii., 502).

New Organo-metallic compounds of bormorn. G. Perrier describes new organo-metallic compounds of bormor, camphor. The first is formed by combination of bormor with analogum chloride, at a temperature of 110° or above. A liquid is thus obtained which on cooling forms yellow camphor. When this mass is boiled with water, the crystals of the new compound are said to correspond to the formula (C₆H₄O₃)₄AlCamphor under similar conditions yields a compound in small plates, having the formula (C₆H₄O₃)₄AlCl₄, and melanocamphor with aluminium chloride forms a yellow methanol that is unstable when exposed to air or moisture (Comp. rend., cxiv., 281 and 373).
It is found by H. Jackson that many substances which are \textit{phosphorescent} remain so when prepared in as pure a condition as possible, but the brilliancy of the phenomenon is influenced by the method of preparation of the compound. Thus, lime prepared from pure precipitated calcium carbonate in the crystalline condition was strongly phosphorescent, but when the carbonate was rapidly treated while in the amorphous condition, the lime from it hardly glowed at all. Similarly variable results were obtained in the case of baryum carbonate, and it would, therefore, appear that, "according to the conditions of its preparation, an apparently pure substance may or may not be phosphorescent, or the colour of its glow may not always represent rays of the same range of wave-length" (Journ. Chem. Soc., cxxix., 734).

A. Bach demonstrated some time ago, that, under the influence of solar radiation, carbonic acid is decomposed in chlorophyll-bearing plants into formaldehyde and an oxidising body whose action is analogous to that of hydrogen peroxide, but a number of experiments recently performed, when the usual reagents for the latter compound were applied, fail to prove conclusively that inactually exists in plants (Comp. rend., cxix., 366).

Professor E. S. Bastin finds that the starch grains in different species of \textit{Ocase}.-Ariba, Tabasco, Saraiva, Bahia, Machalle, Grenada, \textit{Trinidad}, Mana, Tobo, Java and Cappoto are essentially alike, and agree with the following general description:—Grains spherical, or nearly so, when simple; hilum central, usually quite distinct and sometimes fissured; fissure simple and straight, or curved, angular, or stellate; one or two usually distinct lines about the hilum, but no other marks on the grain, some of which may be compound. Though closely resembling each other, the starches of the \textit{oases} are quite different from those of drugs generally, and sufficiently characterised to be distinguished from starches added as adulterants. The grains vary from 1.8 to 10.8 in diameter, and they show a structure that is very distinct for such minute structures (Am. Journ. Pharm., ixvi., 369).

In a paper written in Russian, K. Purjewicz shows that the decomposition of organic acids is always taking place in plants, but is especially favoured by (1) the influence of light; (2) the influence of a high temperature; and (3) continuous oscillation of light at the ordinary temperature. A production of organic acids takes place in \textit{Plants} in the dark when the temperature is not high (12° to 15°C.), but is dependent on the previous formation of carbohydrates in the light, and results from their incomplete oxidation. Further oxidation destroys them, with production of carbon dioxide. The acid formed in the \textit{Oases} is malic; in \textit{Pelargonium} and \textit{Oxalis}, oxalic; whilst in \textit{Robinia}, tartaric and citric acids are used. Malic acid is the most easily decomposed by strong light and high temperature; next, gallic and tartaric acids; while citric acid is the least stable (Beilage zum Botanischen Centralblatt, 84, p. 368).

Irrito-contractility in \textit{Plants}.

In a lecture delivered at the Biological Laboratory of Wood's Hall, Mass., Professor J. M. Macfarlane described experiments made on sensitive plants, from which he draws the conclusion that in the animal, as in the vegetable kingdom, we have to do with a true contractile tissue. In the higher plants this tissue is made up of cells, each consisting of an irritto-contractile protoplasmic sac enclosing a quantity of sap, each cell being joined to neighbouring cells by protoplasmic processes which pass through minute pores in the cell-walls. Irrito-contractility may be started by stimuli of a mechanical, chemical, thermal, luminous, or electrical nature. In the case of mechanical stimuli, like that of the leaves of \textit{Dionaea}, two successive stimuli are necessary to start contraction. The contractile tissue is not limited to the bristles, but extends over the whole upper surface of the leaf. The seat of the contractility is unquestionably the vacuolated protoplasm, and not the cell-wall, as held by some writers. The degree of contraction of an organ is proportional to the relative molecular activity of the protoplasm, and to the strength or continuity of the stimulus. There is a very close analogy between the sensitiveness displayed by tendrils and by the tentacles of \textit{Drosera}, both being sensitive to contact as well as to impact.

Fungi of \textit{Favus}.

Drs. Bio and Jessner have investigated the various forms assumed by \textit{Achorion}, both in the native state and under cultivation, and have arrived at somewhat different conclusions. According to Bio the fungus consists of a mycelie composed of branching hyphes, which produce spores. The best staining reagents are eosine and hematoxylin. Under cultivation the three so-called species, \textit{Achorion entythrix}, \textit{A. atacton}, and "Bio's fungus," yielded identical results. The parasite enters the hair-sac, finds its way between this and the surrounding peripheral portion, raises up the epidermis, and is seen through the raised epidermal layer as a yellow dot. He considers that there is no ground for the conclusion that there are several favus fungi. Dr. Jessner, on the other hand, while identifying \textit{Achorion atacton} and \textit{A. entythrix}, regards \textit{A. dikroon} and \textit{A. schenhelinitis} as distinct species. He thinks it possible, however, that the different species may have the same origin, and may be the final products of a metamorphosis, the result of the influence of varying vital conditions (Centralb. für Bakt. und Parasit., 1894, pp. 69-71).

Two years ago, A. Straud described a method of investigating the chlorophyll sinites of green plants by separation into groups (see Pharm. Journ. [3], xxlii., 42). Continuing his researches on this subject, he finds that living lucerne, \textit{Medicago sativa}, contains about 30 Mgr. of green pigment per kilo., and that this pigment contains four distinct varieties of chlorophyll, descriptions of which are given in his paper (Comp. rend., xix., 289).

\textbf{APPLICATION FOR A PATENT FOR A MEDICINAL COMPOUND.}

The following appears in the official list of applications for June 23, 1894:—

12198.—\textit{Medicinal compounds for the treatment of Gonorrhea}. By William Henry Greer, 89, Chancery Lane, W.C.
RAPID FILTERING APPARATUS.
The following very simple and effective filtering apparatus has been designed by Mr. George A. James, chemist, of Selby, Cal. A glass tube of any convenient length, having a contraction near its upper end, is connected with the small end of the funnel by a short piece of rubber tube. The lower end of the glass tube is inserted in the bottle or other vessel which receives the filtered liquid, and the funnel is supported by a filter stand (not shown).

The contraction in this case is made by flattening the tube so that its sides approach each other to within a very short distance, say \( \frac{1}{16} \) of an inch. This contraction prevents air from entering the part of the tube below the contraction, and thus a solid column of liquid is maintained below the contraction. The liquid by its weight produces a partial vacuum in the tube, and thus allows the air pressure on the liquid in the funnel to force the liquid through the filtering medium. The rapidity with which the filtering is accomplished depends upon the length of the tube, other things being equal.

In Fig. 2 is shown a modification of the apparatus, in which the tube is contracled evenly all around in two places, leaving a small circular opening instead of a flat one. Experience shows the flattened tube to be preferable.—*Scientific American*.

EXPORT OF GUM FROM JEDDAH.
The exportation of gum is diminishing every year. Jeddah gum is of a good quality, though not equal to that of Kordofan, which is nearly white and more friable than that which is found in this district. But it is not so much any defect in quality that is the cause of the yearly diminishing exportation of this article; it is the tremendous falling off of late years in the demand for gum arabic. I am informed that the chief reason of this is that, in most respects, an admirable substitute for gum arabic has recently been found in Madagascar and in some parts of North America which is infinitely cheaper. In point of adhesiveness the newly-found gum is quite equal to that which comes from this country, though it is far from being so pure. In this latter respect gum arabic is without a rival, and on that account will always be sought for by chemists and others to whom this qualification is a sine qua non.—*Consular Report*.

British Medical Association.

"REPORT OF THE THERAPEUTIC COMMITTEE.

During the past year the Therapeutic Committee have concluded their inquiry regarding the frequency and importance of ill-effects following the use of the three chief antipyrhetic agents—phenoxy (antipyrin), acetanilide (antifebrin), and phenaecin; and they herewith submit their completed report.

A draft of this report was submitted to the Council at their last annual meeting; but in the complete report now presented much new matter has been added.

"The Committee consider that the inquiry has yielded much-needed information, supplying, as it does, clear evidence that, both as regards their frequency and importance, the statements made regarding these ill-effects have been considerably exaggerated, most of all in the case of antipyrin and phenaecin.

"The ill-effects observed, when not obviously due to idiosyncrasy, have in the majority of cases been the direct result of injudicious or excessive dosage. This has especially been the case with antifebrin, with which drug the ill-effects have been the most frequent and serious. The dosage employed by no fewer than three-fourths of observers (four to ten grains) has been habitually excessive, the proper dose of this drug being from one to four grains.

"In view of the issue of a new edition of the Pharmacopoeia, the Committee have thought they would be furnishing valuable information if they ascertained from the Association the extent to which certain of the more obsolete drugs and preparations are now employed. A report containing a list of such drugs has been made to them for their Pharmacopoeia Sub-Committee; and an inquiry to the whole Association is now in course of being issued.

"The Committee has also in the same relation undertaken investigations with regard to the dosage of certain of the older remedies.

"WILLIAM HUNTER, Honorary Secretary."

"Extract from Minutes of Therapeutic Committee, June 29, 1894."

"The following resolution was directed to be conveyed to the Council. The Therapeutic Committee request the Council that they be reappointed, and that they be allowed the sum of $500 (Thirty Pounds) for their expenses during the coming year. They would also request that the names of Dr. C. D. F. Phillips and Dr. W. Hale White be added to the Committee."

OTTO OF ROSES IN BULGARIA.
The yield for 1893 was a good one, and amounted to round numbers to 2000 kilos. (4400 lbs.). Buying prices ranged from 900 fr. to 1100 fr. per kilo, according to quality, and selling prices from 1100 fr. to 1200 fr. per kilo. About two-thirds of the total yield was exported during the year, and the value of that added to the portion of the 1892 yield, which was held over till the following year, would bring the total value of the year's export to at least £65,000.

The otto went as usual to France, Germany, England, and the United States. The outlook for the present year is very promising, and a large yield is anticipated.—*Consular Report.*
THE SALE OF MEDICINAL PREPARATIONS CONTAINING POISON.

THOUGH no positive intimation has yet been received as to whether the defendant in the case of the Pharmaceutical Society v. Armson intends to abandon the hope of securing a reversal of the original judgment against him, it would appear from the tone of a leading article in the latest published number of the Patent Medicines Journal that such is probably the case. It is there accepted that, the strongest convictions to the contrary notwithstanding, the notion that the meaning of the term "patent medicines" in the Pharmacy Act of 1868 was intended to cover all proprietary medicines must now be regarded as entirely exploded. "The case referred to resulted in a great victory for the Pharmaceutical Society, and is one more nail in the coffin of 'patent' medicines. We should be failing in our duty to the great body of our subscribers if we made the slightest attempt to minimise this judgment or to underrate its probable effects. In the future process must abstain from vending any preparation into which any of the scheduled poisons enter as ingredients, and our advice to them is, to at once withdraw every such article from their stock. There should be no delay in taking this step in obedience to the ruling of the powers that be, and my dailying will surely be attended with considerable danger."

It is, of course, very satisfactory to find that the result is thus freely accepted by our contemporary, rough the idea suggests itself that the writer may be somewhat hasty in accepting the result as a foregone conclusion, for the fact not be overlooked that nothing has been settled by the Court of Appeal that was not already decided by the Queen's Bench Divisional Court, the judgment of the latter being simply emphasised without amplification. As a matter of fact, it would be to the interest of all parties concerned were a further notice of appeal lodged and judgment finally delivered by the House of Lords. If this should not be done, however, the result will be final, so far as it goes. At the same time, it would be idle to suppose that the decision will be accepted by all concerned as a settlement of the whole question of the sale of medicinal preparations by individuals not registered as chemists and druggists, and it may be anticipated that the issue will be once more raised in connection with the sale of some less potent preparation than that which was rendered prominent in the case under notice. Be this as it may, however, it is, as already remarked, satisfactory to find that the immediate decision is likely to be honourably accepted by at least a section of those who must be regarded as the actual defendant in the case.

A strong protest must be lodged here against the repetition in the same article of the perverse misstatement that "these prosecutions were instituted by the Pharmaceutical Society with the object of securing a monopoly" in the sale of medicines containing poison. So far from this being the case, it is well known that the Society, though possessing the power to institute such proceedings, took no steps in that direction for a considerable number of years after the passing of the Pharmacy Act of 1868. The first movement in the matter was made by the Treasury authorities, instigated by the British Medical Association, which felt constrained, in the interests of the public, to seek to put a limit to what was regarded by many medical practitioners as a widespread and increasing evil. The result having shown that that which was previously considered doubtful was distinctly illegal, the Pharmaceutical Society was urged, as the only body possessing full powers under the Statute, to take such action in the matter as appeared necessary and desirable. This has been done, and in time the proceedings, which are necessarily obnoxious to all persons inclined to infringe the Statute, cannot fail to result in considerable benefit to the public, whilst a proper recognition of their services and position may be looked for by the medical profession and pharmacists.

PHARMACEUTICAL FELLOWSHIPS.

At the meeting of the American Pharmaceutical Association held in 1922, Dr. F. Hoffman suggested the establishment of pharmaceutical fellowships. He pointed out that in a paper that had just been read by Professor Kremer it was shown that no less than eighteen of the professors teaching pharmacognosy, in the schools of pharmacy then existing in the United States, possessed little or no pharmaceutical education or experience. By
the abolition of school prizes and the endowment of fellowships, he urged that this abnormal condition would in time be changed, as the present generation of teachers might then be succeeded by "men of riper scholastic and pedagogical training, at the same time familiar with the practice and the details of pharmacy from the bottom up to the highest round of the educational ladder."

In a recent number of the Pharmaceutische Rundschau this idea is elaborated by Professor Kremers, who remarks that there is certainly no reason why the pharmaceutical profession should not choose teachers from its own ranks, though at present this appears to be impracticable to a deplorable extent, the reason being, no doubt, that such a limited number of pharmaceutical graduates pursue advanced studies. He considers that the prize system is largely a failure, and that if the money now spent in that direction could be used for foreign or travelling fellowships, it would serve the double purpose of award and stimulus. As awards the fellowships should be granted for original work embodied in a thesis, and in the hope of obtaining it many graduates would remain in college an extra year or more, after completing the prescribed course. Each fellowship would also serve as a stimulus for advanced and original work to all who intended to compete for it, and thus its benefits would not be confined to the actual holder alone.

As regards the conditions attaching to the fellowships, it is suggested that they should be tenable abroad for two or three years. Home fellowships are regarded as undesirable. Much valuable knowledge would of necessity be obtained during a two years' stay at a foreign university; there are also many problems in pharmacognosy requiring a thorough study of the drug-yielding plants in the countries where they are indigenous or cultivated; and other possibilities of such fellowships are innumerable and inestimable. Finally it is pointed out that, if a dozen educated and energetic young pharmacists were thus collecting information and gaining wisdom throughout the world, the schools of pharmacy would be greatly benefited, and in the course of time enabled to select thoroughly competent instructors from the ranks of their own graduates.

PHARMACEUTICAL EXAMINATIONS.

Intending candidates for the Major, Minor, and Modified examinations should note that the Boards of Examiners in England and Wales, and in Scotland, will meet respectively at 17, Bloomsbury Square, London, and at 36, York Place, Edinburgh, in October, for the purpose of conducting the oral portions of the above examinations, whilst the written and practical portions of the examinations will commence in the last week in September in London and in Edinburgh. They must give notice to the Registrar, and pay the fees to him or before September 15 next. The First examination will be held at 11 a.m. on Tuesday, October 9. Candidates must give notice to the Registrar on a printed form of application, which can only be obtained from him, and this notice, together with the fee, must be in his hands or before Tuesday, September 25 next. For full particulars in all cases apply to the Registrar, Mr. Richard Bremeridge, 17, Bloomsbury Square, W.C.

THE USE OF TEETHING POWDERS.

At an inquest held at Wolverhampton last week the evidence showed that a child three years old died shortly after the administration of a teething powder, prepared by a wholesale firm, and sold by a grocer. The contents of the powder are not specified in the report of the case, but the medical practitioner who was called in stated that death was due to tubercular disease accelerated by the administration of the powder, which he considered a dangerous one to be administered without the advice of a medical man. The powders made from the same formula were generally unsuitable for children. The jury returned a verdict to the effect "that deceased died from tubercular disease of the mesenteric glands, accelerated by a powder containing elements of an unsafe character, and that such powder was administered without knowledge of its nature."

AMERICAN PHARMACEUTICAL ASSOCIATION.

The annual meeting of this association will be held at Asheville, North Carolina, on September 3 to 8. The reception on the first day will be followed by a literary and musical entertainment in the evening, and numerous pleasant excursions have been arranged for the subsequent days.

LIBRARY AND MUSEUM IN LONDON.

Members and Associates of the Society should note that the Library and Museum at 17, Bloomsbury Square, will be closed from September 1 to 4 inclusive.

PROCEEDINGS UNDER THE PHARMACY ACT.

At the Gloucester County Court, on Tuesday, W. O. Davis, trading as Davis and Co., proprietor of a small drug store, was sued, at instance of the Pharmaceutical Society, for selling sheep dip containing arsenic, he being an unlicensed person (see p. 188). It was alleged, in defence, that the powder was obtained by the defendant chemist as he required it, done up in packets for sale. There were three offences charged, keeping open shop for the retailing of poisons, not being a registered chemist, and unlawfully using the title of chemist, and penalty of £50 was imposed for each, with costs.
The next paper was on—

**ANIMAL EXTRACTS.**

By C. E. StUART, B.Sc.

Notwithstanding the investigations and statements of continental observers, the employment of extracts of animal origin in the treatment of disease had made but slow progress in England up to 1891. In that year, however, Dr. George R. Murray, of Newcastle-upon-Tyne, treated a case of myxedema by the hypodermic injection of an extract prepared from the thymus of the rabbit, and the phenomenal success which resulted is undoubtedly one main cause of the large amount of attention which has since been directed to various animal extracts. As it is the duty of the pharmacist to make himself acquainted with the origin, nature, and properties of every substance which the medical man may require to use in the treatment of disease, whether it be vegetable, or mineral, I hope the following brief and incomplete memorandums and notes will not be considered out of place as a communication to this Conference.

The hypothesis on which rests mainly the use of animal extracts as curative agents is that of Brown-Séquard, namely, that "all the glands of the body, whether they have excretory canals or not, give to the blood usefull principles, the absence of which is felt when those glands are extirpated or destroyed by disease." Later he, with D'Arsonval, extended this hypothesis to all parts of the body, and proposed to employ in the human being, whenever the action of an organ is wanting, liquids extracted from the same organ taken from animals in good health. Thus the testicle, in addition to its secretion containing spermatocytes, which pass away through the ducts provided for the purpose, is supposed to secrete also a watery fluid which is constantly being absorbed into the blood and acts as an active principle. Consequently Brown-Séquard advocated injection of this fluid into the system whenever symptoms indicated the need for such a tonic.

Again, it is stated that such glands as the ovaries, pancreas, kidney, have in addition to their own excretory functions also an influence on the general physiology of the system, through the medium of liquid secretions taken up from them by the blood. For example, a form of diabetes is believed to be connected with disorder or destruction of the pancreas. Certain animals extirpation of the pancreas produces this form of diabetes. It is not, however, the loss of the pancreatic juice which enters the intestine through the duct of the pancreas to which the disease must be attributed, for ligaturing this canal does not produce the diabetes; hence the inference that the pancreas has an internal secretion which is of importance to the animal economy, and also of the success which follows the introduction of extracts from healthy glands into a patient who is suffering from the impairment or loss of function of his own glands.

As regards the thyroid secretion, the difficulty of isolating any definite substance from it is very great. The inorganic constituents do not present any remarkable feature, and the organic constituents, as a rule, present in small quantity, and tests for their identification are vague and unsatisfactory.

Even if separated and identified, it is not to be assumed that any product is an "active principle" until it has been subjected to careful and prolonged physiological and clinical tests.

The action of these secretions in the system has been assumed by Pochei to be due to the supposed presence in all of them of one principle typically met with in the testicular secretion, to which has been given the name spermone. This is stated to enter the system, and confers its special tonic powers. Spermone is a base which was discovered by Schreiner in the animal semen. It has been shown to be present in the thyroid body, pancreas, spleen, and ovaries, and it appears to be a normal constituent of the human body and circulating in the blood. However active it may be as a general tonic, it cannot, I think, be considered to be efficacious in cases of disease due to arrested function of special glands, such as the thyroid or the pancreas.

Another suggestion is that each gland has its own and the most active principle. Thus, the testicle, with the most scrupulous attention to cleanliness and antiseptic conditions to produce extracts which may be safely used. The required gland or organ must be dissected out from the body with knives and forceps which have been sterilised in the flame of a bunsen burner, and the glass plates, glass mortars, measure glasses, scale pans, and every other article used must be cleaned with soap and water and rendered aseptic by soaking in a 5 per cent. solution of carbolic acid, and rinsing with a plentiful supply of distilled water which has been sterilised by boiling. The hands and arms of the operator should be scrubbed with soap and water, washed in the 5 per cent. carbolic water, and finally with sterilised water.

**Thyroid Extract.**

In making this the formula originally published by Dr. Murray is adhered to, because it furnishes a solution which possesses the advantage of maintaining its activity for a reasonable time, and also because it is essential for the manufacture of a good extract that absolutely fresh glands shall be used.

In preparing the glands it is best to get them cut from the freshly killed sheep rather than to trust to the butcher to send them in at his convenience. Possibly after a few days delay. As regards the small cysts occasionally found in the lobes, the matter they contain is not pus, but seems to be of a fatty nature, they are, however, for the sake of caution, better left out of the extract. Hypertrophied lobes, such as may be active with from two to three or four inches long, should also be rejected.

The lobes after being cleaned from fat and connective tissue are sliced thinly and bruised in a mortar; for every lobe is added 1 C.c. of glycine and 1 C.c. of sterilised water. The mixture is allowed to stand for twenty-four hours, and is then squeezed off through fine calico. The product measures 3 C.c. for every lobe, and is a thick, dull red, cloudy liquid.

For hypodermic use water containing 0·5 per cent. of carbolic acid takes the place of the plain water.

A powder which keeps well may be made by simply expressing the juice from the glands, mixing it with flour of milk, spreading it in thin layers on glass plates, and drying at 80° F. The weight of the dry powder may be made up to 1 gramme for every thyroid lobe employed. This is three times the strength of the liquid extract.

The investigation of the constituents and active
principle of the thyroid gland has had results which are chiefly of a negative nature. According to Dr. Gourlay, 'Journal of Physiology,' vol. xvi., No. 1, the thyroid extract contains—

1. A residue, coagulating at 50° to 57°, precipitable by magnesium sulphate and also by water from the gland poured up with salt.

2. Very little proteid.

3. No mucin, the nucleo-albumin having been mistaken for this.

4. No yellow peptone.

5. Possibly a ferment.

I have confirmed the first four results, but it is to be noted that the biuret reaction, indicating proteose or peptone, "rose-pink colour on the addition of traces of copper sulphate and some sodic hydrate," is readily obtainable if the thyroid lobes are not fresh.

As regards Dr. Gourlay's suggestion, "with all reserve," that the nucleo-albumin may be the active principle since it is found in the peculiar secretion of the gland, because it is the only part of the tissue that resists (partially at least) gastric digestion, I would remark that nucleo-albumin is not peculiar to the secretion of the thyroid but may be obtained from almost any cellular organ, and it remains to be shown that this particular nucleo-albumin has properties differing from that obtained from any other source. Also, that it is quite possible that bodies which are destroyed by artificial digestion may be absorbed into the system through the stomach walls without change.

As regards the presence of a ferment, the powder prepared as described by Mr. White in his paper read before the Conference last year, by precipitating with calcium phosphate an aqueous extract of the gland, is stated to be active, and may contain a ferment. In my own experiments in search of the active principle, the following process has been adopted at the suggestion of Dr. G. Murray. One hundred thyroid lobes were sliced fine and allowed to stand for several weeks in absolute alcohol. The alcohol was poured off and the glands dried, when they were extracted with water. The aqueous extract was evaporated under reduced pressure at 30° C. to a small bulk, and poured into ten times its volume of absolute alcohol, producing a copious grey precipitate. This precipitate was again extracted with water and poured into alcohol, giving a second precipitate of less bulk, on which the extraction and precipitation were repeated and the final alcoholic precipitate was dried and powdered. This process coagulates or gets rid of proteid and nucleo-albumin, together with lecithin and fats, and probably excludes bodies other than a ferment; but as to the proof of this being one, no experiments parallel to those which can be made in the case of others is available. We must wait for physiological proof of its activity, and experiments in this direction are being conducted by Dr. Murray.

The powder from 100 glands weighs 792 grammes.

With respect to an improved formula for the preparation of the secretion of thyroid extract, there is at present no published evidence that any method of preparing it gives better results than Dr. Murray's original formula.

**Brain Extract.**

The method I have used for the preparation of a brain extract has been to take the brain of a rabbit, slice it, and rub it in a mortar with 1 cubic centimetre of glycerin, and 1 cubic centimetre of 0.5 per cent. carbolic acid to every grammes of its weight. Allow to stand twenty-four hours, and squeeze with strong pressure through fine linen. This is somewhat similar to the method of preparation used by Bebes, who made an emulsion of the sterilised brain with five parts of bouillon ('Deutsche Med. Woch.,' July 28, 1892).

The product is a pinkish white emulsion, consisting of almost the whole brain substance, there being left on the linen chiefly membrane. In seventy rabbits I find the average weight of the brain to be 4.2 grammes, the highest being 11.7 and the lowest 2.4 grammes, and the average yield of the cerebrine alpha was 23.5 C.C. The S.G. of the extract is 1.05.

Ten minims of this extract have been injected with good effect in cases of neurasthenia, locomotor ataxy, and other nervous cases.

The preparation contains in solution a little proteid, and in suspension protoplast, lecithin, cholesterin, and cerebrin, and is most interesting on account of its complex character, the definite nature of its chief constituents, and the freedom from irritation and abscess following on the injection of its considerable proportion of solid matter under the skin.

Dr. J. Althaus in his paper on this extract (Lancet, December 2, 1893), which, as above prepared, he calls cerebrine alpha, suggests that its action on the nervous system may be two-fold, and due, first, to the injection of a highly specialised palatable nervous matter; and second, to the decomposition of the lecithin and cerebrin and the liberation of the alkali of the blood into choline, glycerophosphoric acid, and stearic acid. Choline is an alkaloid which acts as an antitoxin by reason of its oxidising action on the blood. In small doses it produces pyrexia. It is an interesting fact in this connection that A. Rul of Paris, has obtained recently results of the use of glycerophosphoric acid and its salts in nervous cases (Lancet, May 5, 1894). Here both the choline and the glycerophosphoric acid may be active in the extract.

**Spinal Cord Extract.**

This is similar in its nature and effects to the brain extract. Its preparation is more troublesome, as the spinal cord must be obtained by carefully removing away the upper portion of the vertebrae of a rabbit with a bone forceps until the whole cord is exposed, when this may be lifted out together with the medulla oblongata; the arachnoid membrane may readily be stripped off and the cord divided at the root of the brain extract. It is characteristic of this myeline alpha to distinguish it from the histological "myeline," a constituent of the central nerve fibre. The average weight of the spinal cord I find to be 4.68 grammes, the highest being 6.2 grammes and the lowest 3 grammes, and the average yield of myeline alpha was 123 C.C.

**Spleen Extract.**

On opening the body cavity of the rabbit the spleen is the usual position for dissecting, and moving the bones to the left, the spleen will be seen as a narrow red-brown organ lying just behind and across the stomach, which is easily dissected away from the peritoneal membrane in which it is folded. It has characteristic bright red colour and varies considerably in size, being from 1 to 2 inches in length and from ½ to ¾ of an inch in diameter. Weighs on an average 89 grammes. An extract may be prepared from it by rubbing up with enough of a mixture of equal parts of glycerin and ½ per cent. carbolic acid to make a suspension, washing through linen, and diluting it with 1/2 for each spleen. This extract has been used medically in doses of ten minims in leukocytopenia, enlarged spleen, and Hodgkin's disease.

**Supra-renal Extract.**

Immediately behind and just above the kidney the rabbit will be found on either side the supra-renal capsule, a small oval pale yellow body, which is easily dissected out. In cases where the animal is very fat the organ is not so readily seen on inspection, but a small amount of dissection will
The presence, and when once it is recognised and known it cannot afterwards be overlooked. Each supra-real body weighs on an average 25 grammes, and on cutting across it is seen to be composed of two distinct parts, an outer, thicker, central part of yellowish, striated, radially, and an inner, thinner, medullary part of darker colour. On bruising the bodies in the mortar the substance has a yellowish-brown granular appearance. The extract has been made by slicing and bruising the capsules and adding a sufficient quantity of equal parts of glycerin and alcohol. The red marrow is then expressed as above, 4 C.c., or 1 fluid drachm for each supra-real body. This has been used in 10 minims hypodermic doses in Addison's disease.

Pituitary Body Extract.

The pituitary body is a small pink mass at the base of the brain. It is a very small body; in the sheep it weighs 76 grammes, and this is a convenient source for making the extract. The sheep's head is opened, and the brain removed, all nerves and blood vessels on the underside being divided with a scalpel. The pituitary body will be found to have been left in the skull in its little depression almost covered over with thick membrane, which has to be cut away before the pituitary body can be freed. It is treated as the brain, and has been used in acromegaly.

Pancreas Extract.

The pancreas of the pig is the most convenient for making extract. It should be most carefully freed from fat, finely divided, and treated as brain extract. It furnishes a milky extract, which contains, besides the digestive ferments of the pancreas, the special secretion which preserves the organs from diabetes.

Thymus Extract.

This gland may be obtained from the sheep or pig; it is important that it should be taken from a young animal, as it atrophies in the adult. When treated as the brain it yields a thin, whitish extract, which has been used in similar cases to the thyroid extract, but with indifferent results.

Kidney Extract.

In making this extract, the kidney should be cut open and several deep incisions made into its substance, so as to allow of a thorough washing out of the pelvis of the kidney to free it from excreted matter. It may be then chopped fine and treated like the brain. I should like to remark here that as we know so little of the physiology and function of some of these organs, and absolutely nothing as to what is the active principle or principles in these extracts, an arbitrary standard of strength must for the moment be adopted and the dose adjusted to these strengths. I have been guided by the unqualified success which attended the strength adopted by Dr. George Murray for thyroid extract, and have made only slight modifications to suit the convenience of size and weight in other organs.

Bone Marrow Extract.

The development of red blood corpuscles seems to be a function which is chiefly carried on by the cells composing the red marrow of bones (Halliburton, "Gen. Phys. Path.," p. 285). It is natural, therefore, that this promising field for the manufacture of an extract should be explored for this patient. A paper was read before the International Medical Congress in Rome (Brit. Med. Jour., June 2, 1894) a paper in which he showed the favourable result of giving red marrow by the mouth in quantities of three ounces daily in case of pernicious anaemia.

As the cells of the red marrow from which the red corpuscles are derived are met with chiefly in the cancellous portion of the bones, such as the head or base of the femur, and other long bones, and less numerous in the actual fatty marrow in the hollow shafts of these bones, it is to be expected that an extract from this cancellous tissue should prove stronger in its action than the marrow itself, and therefore smaller doses be required. Dr. J. Dixon Mason publishes a note on this subject in the Lancet, March 10, 1894. Following his indications, an extract may be prepared by splitting the femur of a young animal, say the cat, and gouging or scooping out the red bone marrow from the head of the femur. Pounding this fine dust in a clean iron mortar, and macerating the mass for a few days with glycerin in the proportion of one in ten with frequent agitation, when the extract is filtered through glass and made up by washing with glycerin to the necessary volume.

As the process of development of the red corpuscles is one in which the nucleated cells of the red marrow are altered, and assuming a rounded shape become blood disc and enter into the circulation, or according to another view, one in which these cells are once blood disc and not be neglected, Dr. Fraser read a explanatory hypothesis of the action of this extract must be that it contains a substance which either stimulates the energy of marrow cells already in existence, or encourages the formation of new ones.

Tissue Extract or Orotic Fluid.

I have left this until last, because it is an extract in which I have simply followed the strength (one in ten) and process published by Professor Brown-Séquard in the Poggendorff's Annalen of 1867. Two hundred used ram's testicles divested of their outer membranes, and to each gramme weight added 3 C.c. of glycerin and 6 C.c. of 0.5 per cent. solution of boric acid. After macerating twenty-four hours, this mixture is filtered through sterilised filter paper, and then finally sterilised in the D'Arsonval apparatus, which has been described in the Pharmaceutical Journal (see vol. iii., 1034).

The President said the author of the paper was not present, he regretted to say, but as animal extracts were being demanded by medical men, it became the pharmacist not only to be able to prepare them, but to qualify himself by a knowledge of physiology and the practice of whatever the medical men required. Mr. White, of St. Thomas's, had published some work in connection with the thyroid gland, and they had seen allusions in which editors had run greatly in advance of Mr. White's own papers about it, especially with regard to the active principle. He was not sure they always knew what they meant when they talked about the active principle, but it was well to remember that not only the pharmacist, but the chemical physiologist or physiological chemist, was working in an entirely new region, and a region of intense interest scientifically. Nothing approaching it in interest, from a scientific point of view, had ever come into his pharmaceutical life. How long it would be before they received any light on these great problems he did not know, but he did know that it was necessary for pharmacists to be capable, in connection with these animal compounds, and even bacterial compounds, of producing whatever the medical man required in such a way as to answer and smile, and to refer to the time when various animal excreta were used, probably with a certain amount of superstition, at the same time the justification of experiments with regard to other animal compounds was found in the remarkable success to which he had already referred. With regard to the care required he could not say any words strong enough to impress
on everybody who had to deal with those things not to relax it. The slightest decomposition which might occur in the thyroid glands was capable of producing the most tremendous effects of an undesirable character, and those who had read any literature on the subject would recognise that it was not a thing to be left to chance. The author, on the other hand, the pharmacists who managed these things took on himself the responsibility from beginning to end, at any rate until they knew more about the chemistry of the subject. The author himself, for several reasons, had preferred to postpone this paper for some years. At the same time, hurried as it was and imperfect, it was a valuable contribution to the Conference, and pharmacists could not begin too soon to turn their attention to things which might at any moment assume greater importance than that one extract had.

Dr. Ridley said one would have thought that a preliminary test for the presence or absence of ptomaines would have been sufficient to insure the pharmacists dealing with a satisfactory gland, but from Mr. Stuart's view it would appear that it would be necessary to go further back than the presence or absence of ptomaines, and to the glands, gathered from the paper that it was necessary to insist upon the absence of albumoses and peptonises, or, at any rate, bodies giving a biuret reaction, before you could be certain that the thyroid gland was one which would be safe. If that were so, it was of great importance, and the conclusion arrived at by Mr. Stuart ought to be of great value to those engaged in making these preparations.

Mr. Gerard said those who might wish to make a preparation which was perfectly accurate and reliable for internal administration might do so by taking fresh glands, carefully mincing them, removing as much fatty matter as possible with the knife, then washing out any remaining fatty matters by means of such solvents as ether or benzol, spreading the gland out thinly on a sheet of glass, and submitting it to a drying process at a low temperature. At the same time it could be sifted or mixed with a certain amount of well prepared sugar of milk; it might then be bottled, and you would be sure of having a reliable preparation which any pharmacist might prepare for himself. That, however, should not be supplied for making hypodermic injections. In such circumstances it was essential to follow out perfectly the careful process suggested by the author.

Mr. Williams said in making the preparation of the thyroid in powder a convenient method was to press the gland in a clean press, when the juice might be conveniently collected and allowed to form a thin layer on glass plates or on a large photographic plate, and dried at a low temperature. It readily scaled, and that scale could be powdered and readily used. Of course, there was much greater difficulty in following out all the precautions necessary in order to make a preparation which could be useful and safe for hypodermic injections.

The President said he was not competent to reply on behalf of the author of the paper, though he had paid a great deal of attention to the subject, but in reply to Dr. Ridley he might say it was not a question of the presence of ptomaines, but of the avoidance of danger, and it was safer to eliminate danger from the beginning than to trust, in their present condition of knowledge, to checking themselves by chemical means at any subsequent stage.

THE NEXT TWO PAPERS WERE CONSIDERED TOGETHER—
LEONURUS CARDIACA.

BY R. M. HOLMES, F.L.S.,
Curator of the Museums of the Pharmaceutical Society.

My attention was first directed to this plant by its very bitter taste. The name 'Cardiac' is derived from its specific name suggested that (like Convallaria) it might possibly possess some beneficial action on the heart, and that it would be worth while to subject it to a chemical examination, at all events so far as to determine whether its properties are due to an alkaloid or a glucoside, as the bitter principle has not been isolated. The plant grew like a weed in the sandy soil of my garden, sowing itself everywhere, so that I was able to supply sufficient for a preliminary investigation, which Mr. W. A. Naylor kindly undertook.

Concerning its history as a medicinal plant there is not much to be said. The earliest herbal in which I have been able to find an account of the properties of the plant is the 'Botanicon' of Theodore Dorstenius, dated Frankfort, 1540, in which, on p. 65, an excellent figure of the plant is given. Ten years before it was called Marrubium mas by Bruelius. By other authors it was called Marrubium nigrum, whilst Ballota nigra was distinguished from it. It is doubtful whether the plant was known to possess medicinal properties by the early Arabians and Greek physicians. Dorstenius says that it is called cardia because it powerfully relieves palpitation and pain in the region of the heart. Culpepper, in the 'English Physician Enlarged,' published about one hundred years subsequently (1668), writes: 'There is no better herb to drive melancholy vapours from the heart, to strengthen and to make the mind cheerful, blithe, and merry. The powder thereof to the quantity of a spoonful drunk in cold water is a wonderful help to women in sore travail, and also for suffocations or risings of the mether, and from these effects it most likely got the name of motherwort.' He also states that it possesses diuretic and emmenagogue properties, acts as an expectorant, and kills worms, and also relieves cramps and convulsions. In J. Hill's 'Flora Britannica,' published about a hundred years later (1760), which is interesting as containing the first Linnean flora published in England, the author remarks (on the authority of D. Bowle) that the plant is good for hysteric.

But Leonurus cardiaca seems to have been rarely used by medical practitioners. The only list of simples in a London pharmacopoeia in which I have found it is that published in 1721. It also occurs in the Paris Codex of 1758. Nevertheless, its reputation as a cardia remedy appears to have extended to the Continent, since the names in French (Agrispaume cardiaque), German (Herzgespann), and Dutch (Hartgespan) all indicate the same property.

In answer to inquiries I have made as to its present use as a herb, I learn from Messrs. Potter and Clarke that it is still used to a considerable extent (about 1 ton annually) in England; also in the United States, and in Germany, and to a small extent in France. It is supplied in the form of herb, fluid extract, and extract. Mr. Rensom also informs me that the extract is sent to India where it is used for suppressing hysteric and, as he says, is now offered to supply herb, fluid extract, or extract for the purposes of therapeutical and physiological investigation.
EXAMINATION OF LEPUSUS CARDIACA.

BY W. A. H. SAYLOR.

More than a year ago Mr. E. M. Holmes, F. L. S., Curator of the Museums of the Pharmacetical Society, handed over to me about twenty pounds of fresh motherwort, which he had grown, with the request that I would subject it to a general examination.

The fresh herb was pressed, and to its juice was added 50 per cent. of rectified spirits as a temporary preservative. After making a few preliminary tests, the following mode of procedure was decided upon. The "success" was evaporated over a water-bath to a soft extract (A). This extract was treated by agitation with successive portions of absolute alcohol, and the several portions were united and distilled, leaving two residues, one soluble and the other insoluble in alcohol.

A. Residue Soluble in Alcohol.—It was noted that small crystals separated out during the distillation of the alcohol, these on examination proved to be potassium chlorate. The alcoholic residue was exhausted with ether in the cold, which, after evaporation, left a reddish-yellow mass that was soluble in chloroform, alcohol, and ether, and insoluble in petroleum ether, benzol, and water. It was intensely bitter, and could not be provoked into crystallising from any of its solvents (1). The portion which did not dissolve in the ether was treated with a 5 per cent. aqueous solution of sulphuric acid, in which it was for the most part soluble, filtered, and the filtrate shaken up with chloroform. The chloroformic residue presented the appearance of a dark reddish-brown, bright, hard varnish, intensely bitter. Ether removed the principle to which is owed its bitterness, when it was found to correspond with As (1). The chloroformic residue not taken up by ether after re-solution in chloroform and evaporation was brittle, and by triturating yielded a dark brown powder, soluble in alcohol, from which it could be recovered only in an amorphous form (2).

The acid solution was next rendered alkaline with ammonia, and agitated with chloroform. The extract left after the re-solution of the chloroform, when purified from ether, was free from bitterness, of a pale straw colour, not sensibly alkaline, readily soluble in acidified water, alcohol and ether. So far all attempts to obtain it in a crystalline form have failed. Its solution in acidified water gives copious precipitates of the carbonates; it was converted into a nitro-compound. Thresh's reagent, phosphomolybdic acid, platinum perchloride, chloride of gold, iodide of cadmium and potassium, potassium metatungstate, and picric acid. With mercuric and potassium iodide it gives no reaction. It may be purified by precipitating its solution in weak hydrochloric acid with solution of iodine and potassium iodide, and recovering it from the precipitate by decomposition with sodium thiosulphate (3).

The portion which, in the first instance, was not dissolved by the 5 per cent. solution of sulphuric acid yielded to chloroform a bitter principle, which had the characters and solubilities of As (1). The aqueous alkaline liquor, after neutralisation with sulphuric acid and evaporation to complete dryness, and subsequent treatment with absolute alcohol, left a dark-looking hygroscopic residue, which did not possess characters that would entitle it to be described by a more definite name than "Residue insoluble in alcohol."—This was treated with water to exhaustion and the solution filtered. There was left a small grey pellucid residue, which consisted of lime phosphate. The aqueous filtrate, after evaporation to a convenient bulk, was precipitated with lead acetate, and the precipitate was collected, washed, and dried. The precipitate after suspension in water and the lead filtrate were decomposed by sulphuretted hydrogen. After removal of the lead sulhide, the separate filtrates were evaporated to a treacly consistence and marked "aqueous extract" and "aqueous precipitate extract" respectively. The aqueous precipitate extract was strongly acid; it was dissolved in water, neutralised with soda, and precipitated with calcium chloride solution, shaken vigorously, allowed to stand, and filtered. The filtrate was boiled, when a further separation took place, and was filtered hot. The filtrate when cold was shaken with three times its volume of alcohol, which caused an immediate precipitate. These several precipitates were recognised as tartrate, citrate, and malate of lime. The filtrate from the last-named precipitate was evaporated to dryness and exhausted with boiling alcohol, which sufficed to remove every trace of calcium chloride. The residue was unaffected by any solvent except water, in which it dissolved completely and readily. When dried over a water-bath it was a reddish-brown, hard mass, which by exposure gradually softened through absorption of moisture. It had a sour, slightly saline taste.

A. Aqueous Extract.—This semi-liquid extract was treated with four times its volume of alcohol, the alcohol was recovered by distillation, and the remainder evaporated, when there was left a residue of a bright dark red colour, bitter, and completely soluble in wa-er. After removal of the bitterness by ether it was dissolved in water, precipitated with lead subacetate, and filtered. Both the filtrate and precipitate were decomposed with sulphuretted hydrogen, filtered, and evaporated. The portion precipitable with lead subacetate presented the characters of pectinous substances, and the portion not precipitable with basic acetate was simply extractive.

The residue of the aqueous extract left after treatment with alcohol was dissolved in water and precipitated with lead subacetate. Both the filtrate and precipitate were decomposed with sulphuretted hydrogen and severely concentrated to a thick consistence by evaporation. The lead filtrate extract, after standing a few days, was studded with crystals. These crystals, when isolated from the extract in which they were imbedded, were in the form of thin needles, colourless, very soluble in water, insoluble in alcohol, and consisted of a potassium salt of an organic acid. A solution of the salt was not precipitated by barium or calcium chloride or lead acetate. It was converted into a nitro-compound, which was decomposed with dilute sulphuric acid. Unfortunately, through an accident at this stage, sufficient crystals were not recovered to admit of their identification.

B. The marco left after expression of the juice was carefully dried and exhausted with rectified spirit. The spirit was distilled off, and the resultant extract
was treated at the temperature of the water-bath with a 5 per cent. solution of sulphuric acid until the soluble portion ceased to react with a solution of iodine in iodide of potassium. After filtration, the filtrate was adjusted to the reaction of ammoniacal lime by agitating with three successive quantities of chloriform, which were separated, mixed, and distilled. In its appearance, its indifference to litmus, its solubilities, its refusal to crystallise, and its reaction with alkaloidal reagents, it corresponded with As (3). The residue of this solution not-soluble in sulphuric acid, after washing with water, was dried over a water-bath and exhausted with petroleum ether. That which did not pass into solution was treated with ether. The residue from the petroleum ether was largely soluble in absolute alcohol, and after filtration and evaporation from this solvent there was left a fixed liquid oil, green from the presence of chlorophyll, soluble in ether, bluish-pigment of carbon and alcohol. The residue from the ether yielded to bluish-pigment of carbon a considerable quantity of a soft resin, soluble in chloriform. There was finally left an amorphous, blackish, crumbly substance, upon which neither the reaction of alcohol nor its heat reaction was exerted. Alcohol removed therefrom traces of chlorophyll, citric acid and malic acid, and chloriform withdrew a hard, bright, brittle, resinous principle, which after washing with ether could be readily reduced to powder. In its characters and solubilities it agreed with As (3). The insoluble residue was not further examined.

C. This consisted of the extract obtained by exhaustion of the marc from B with ether, and distilling off the solvent. Petroleum ether dissolved the major portion of this extract. That which did not pass into solution was treated successively with alcohol and chloriform. Of these solvents the former removed a hard, chippy substance, which yielded to ether a bright waxy residue, while the portion insoluble in the ether was brittle, and corresponded with As (2); the latter solvent (chloriform) withdrew a substance more akin to a wax than a resin. The petroleum ether residue was a mixture of fatty and waxy constituents. It was saponified by prolonged boiling with a solution of potash in alcohol, allowed to cool, and the matter which separated was collected on a filter and washed with rectified spirit (C 1). To the filtrate water was added, and the alcohol evaporated, the residue washed several times with ether, which on evaporation gave a yellow crystalline residue (C 2) that readily dissolved in alcohol and gave on cooling a crystalline magma which under the microscope was seen to consist of minute needles arranged in the form of rosettes, and affected by polarization in a manner similar to fatty acids. This was evidently a decomposition product of the wax. The filtrate, after the withdrawal of C 2, was acidified with hydrochloric acid and warmed. The separated and crystalline fatty acid when cold was collected and purified from petroleum ether. The portion not taken up by petroleum ether was shown in chloriform agreement in its characters with As (2).

D. The marc from C was exhausted with cold water, and the liquor evaporated. In this extract, containing a considerable quantity of a Fehling reducing substance, nothing of importance was found that has not been referred to as present in the marc taken from the other portions of the plant. The total results obtained may be compressed into a statement of the constituents separated in the course of the examination. They are: **Definite**—potassium chloride, calcium phosphate, citric, tartaric, and malic acids; **Proximate**—bitter principle, hard resin soluble in chloriform, insoluble in ether, soft resin soluble in chloriform and ether, alkaloidal substance, potassium salt of an organic acid, fixed oil; wax soluble in petroleum ether, wax insoluble in petroleum ether; extractives, one soluble in alcohol and water, two soluble in water only.

Mr. DRouce said he believed motherwort was first mentioned as a British plant in Gerrard's "Herbal," and the place where it was found to grow was near Oxford.

Mr. WILLIAMS said an American author had contributed an examination of motherwort, but his results did not seem very satisfactory. He would ask if Mr. Naylor looked for volatile oil, because such oil was mentioned in the communication to which he referred.

Mr. HOLMES said quite probably the American plant examined belonged to a different species.

Mr. MARTINDALE said he expressed some juice from some plants which Mr. Holmes had sent him, and had sent the extract to Aberdeen for physiological investigation, but he had not yet received any reply.

Mr. GERARD said Mr. Naylor did not mention whether he had examined these plants for glucosides, but he had examined them that he thought might be a glucoside, for it often happened that you got a sort of non-alkaloidal bitter principle, which when freely examined turned out to be a glucoside. Again, he would ask him whether the residue which he had shown represented the whole amount obtained from the 20 lbs. examined, or only a fraction.

Mr. NAYLOR said it was only a fraction.

Mr. GERARD said sometimes a plant when worked in large quantities would give a small amount of matter and reactions of an alkaloidal character, which would not give a precipitate with Maye's reagent. In such cases, where the yield was exceedingly small, it was scarcely worth wasting time on further investigation. It might often turn out that the active principle was to be found in some other body rather than in the small trace of alkaloid present.

Mr. ALOUCK asked if Mr. Naylor had examined for caffeine, seeing that that corresponded with many of the alkaloidal tests, except Maye's. He could not see any connection between caffeine and motherwort.

The PRESIDENT said he was sure they would all wish to emphasise the vote of thanks to be given to the authors of these papers. Those who knew the amount of executive work done by Mr. Naylor would know that they owed him a large debt of gratitude for having found time to prepare a paper of this sort. He would say, with regard to Mr. Gerrard's suggestion that it was labour wasted when they found such a small quantity of alkaloid, that, as a question of scientific interest, it would be a pity to throw away any article from which they obtained even 5 grains, which might be an active principle, and might throw some new light on some chemical or physiological problem.

Mr. NAYLOR said, after some little experience of what was known as plant analysis, he had learnt to be very cautious in speaking of any principle or constituent one might have isolated as definite. For instance, this bitter principle he had managed to purify by various solvents, but at the present time it gave a reaction with Fehling's solution, and he could not possibly say whether that was due still to some adhering impurity or to its reaction with the dissolved material he had produced were taken from a bulk. In some instances he had fair quantities of these separate constituents, and simply brought these samples to represent them. He did not know the amount of alkaloid separated, but he should think it was quite sufficient to encourage one to extract the large supply from 4 cwt. or more of the plant. Of course he had regard to the fact that it might be caffeine. 

{September 1, 1894}
from the negative reaction which Mr. Aloook mentioned, but he was unable to identify it as such.

The following paper was next read—

THE CONDITIONS OF PAPAINE DIGESTION.

BY S. RIDMAL, D.SC. LOND., F.I.C.

Since communicating some notes on papain digestion to the North British Branch of the Pharmaceutical Society (Pharm. Journ., April 7, 1894), I have had an opportunity of further studying the behaviour of this interesting vegetable ferment, and the fresh results which I have obtained seem to clear up some of the points which my earlier examination showed to be still doubtful. The pure ferment has not yet been isolated, and at present it is impossible to determine the amount of papain in commercial samples. In this respect papain resembles pepain, and its value as an aid to digestion can only be measured in terms of its relative activity to different brands of pepain. The term papain, although strictly belonging to the pure ferment, is also used to denote the mixture obtained from the insapulated juice of the papaw fruit, and as an equivalent to papainin, which seems to be another preparation from the Carica papaya tree. The commercial papain used in these experiments appears to contain a uniform amount of active ferment, as the different samples I have examined do not differ very much from one another in digestive activity.

In most of the earlier work with this ferment, comparisons have been made with pepain under conditions which are known to be conducive to the rapid digestive action of the animal ferment, ignoring altogether the fact that papain from its mode of occurrence and general properties may have inclinations favourable to its action which are altogether different to those which obtain for pepain. It has long been known, for example, that papain, unlike pepain, digests in an alkaline fluid, and this fact alone shows that it is more strictly comparable to trypsin than to pepain. Its analogy to trypsin cannot, however, be pressed too far, since it does not appear to possess a fat splitting power. In some recent experiments on the action of papain on milk and cotton seed oil emulsion, I found that even after four hours at a temperature of 40° C. there was no evidence of the production of any fatty acid, so that, unlike trypsin, papain does not possess the power of hydrolysing fats. I have been unable, also, to find any information as to its action on the carbohydrates, although from its vegetable character one might expect it to possess some diastatic action. It would be interesting to determine whether any of these ascriptions apply to papain in any amyloytic action, as such an investigation would aid in determining whether there are several enzymes present in crude papain. Although its hydrolytic action on fats and carbohydrates is thus somewhat remote, there is no doubt of the well-marked proteolytic in most of the cases in which papain possesses. It is the purpose of the present communication to furnish a more closely the conditions which are the most favourable for its proteolytic action.

1. Influence of time. Rate of digestion.

In these experiments coagulated white of egg was employed as the material for digestion. The quantity of water present in the coagulum was determined in the ordinary way by drying at 100° C. until the weight was constant. Weighed portions of the same sample were then transferred to wide-mouthed bottles fitted with corks, and three times the weight of distilled water added, together with one per cent. of papain. The bottles were then placed in a chamber heated to 37° C. and removed after different intervals of time, when the contents of the bottles were transferred to a muslin filter, washed, dried, and weighed. The following table shows the results obtained in two such complete experiments:

<table>
<thead>
<tr>
<th>Time in hours</th>
<th>Papain 20</th>
<th>Papain 21</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>25</td>

<tr>
<td>3.5</td>
<td>20.9</td>
<td>3.2</td>
</tr>
</tbody>
</table>

It will thus be seen that in both cases in less than an hour 75 per cent. of the coagulated albumin had been converted into a soluble form, and that at the end of three hours the digest was practically complete. For practical purposes it may be regarded as completed at the end of that time. It will also be noticed that, although both these samples up to the end of the first hour had approximately the same rate of digestion, the action was pushed to a far greater extent by sample 21 than by sample 20 after this interval of time. The slower rate obtained with papain 20 was due to the fact that the albumin was coagulated in the bottles used, and thus exposed a smaller surface to the digestive action.

2. Influence of temperature.

In these experiments egg albumin coagulated and squeezed through wire gauze was employed, and the bottles containing a mixture of 15 grammes albumin, 45 C.c. water, and 0.15 gramme papain were kept for two and a half hours at the different temperatures given below:

<table>
<thead>
<tr>
<th>Temperature</th>
<th>Papain 26</th>
<th>Papain 27</th>
</tr>
</thead>
<tbody>
<tr>
<td>26° C.</td>
<td>68.6</td>
<td>65.1</td>
</tr>
<tr>
<td>32° &quot;</td>
<td>68.0</td>
<td>64.1</td>
</tr>
<tr>
<td>38° &quot;</td>
<td>67.2</td>

</tr>
<tr>
<td>42° &quot;</td>
<td>73.5</td>
<td>67.7</td>
</tr>
<tr>
<td>45° &quot;</td>
<td>73.5</td>
<td>67.7</td>
</tr>
</tbody>
</table>

In both cases the maximum amount of digestion took place when the temperature was 40° C., whilst at higher temperatures than this the activity of the papain rapidly diminishes. Between 30° and 40° C. the rapidity of the action gradually reaches its maximum. It is interesting to note that the temperature at which the digestive action is most pronounced is approximately the temperature of the blood. This is a remarkable fact, and the coincidence which it is difficult to explain. Diastase, the other vegetable ferment which has been studied carefully, does not begin to lose its power of hydrolysing starch until the temperature of 65° C. is reached. I have not yet had an opportunity of examining bromelin, the vegetable ferment which appears to be most allied to papain, but it will be interesting to see at what temperature its activity is the most pronounced.

3. Influence of the amount of ferment.

Although 1 per cent. of papain has a very marked digestive action, if the amount of ferment relatively to the amount of proteid to be digested be increased, there is a slight increase in the amount of digestion that takes place, as shown by the following results:
There is therefore but little advantage to be gained by increasing the amount of ferment above 1 per cent. on the wet proteid to be digested.

5. Influence of the amount of water present.

In these experiments 15 grammes of egg albumin, prepared as already described, were employed, and 0·15 grammes papain, with varying amounts of water. Digestion was allowed to proceed for three hours at 40° C.:—

![Table](image)

The same experiment with distilled water, under the same conditions, left 78·0 per cent. undigested. It is therefore evident that 0·1 per cent. of any of these acids has little influence on the amount of digestion.

(c) Influence of Salt.—M. Dastre has lately pointed out that the halogen salts in large quantities (sodium chloride, sodium fluoride, and ammonium chloride) induce a digestive change in fresh proteids in the absence of any ferment. In gastric juice the amount present is about 0·4 per cent. With papain an increase in the amount of salt seems to slightly retard solution, thus:—

<table>
<thead>
<tr>
<th>Percentage Undigested after Three Hours in Presence of</th>
<th>0·1 p.c. NaCl sol.</th>
<th>0·25 p.c.</th>
<th>0·5 p.c.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Strength of Acid</td>
<td>Tartaric Acid</td>
<td>Boric Acid</td>
<td>Hydrobromic Acid</td>

</tr>
<tr>
<td>0·25 &quot;</td>
<td>71·7</td>
<td>73·3</td>
<td>75·2</td>
</tr>
<tr>
<td>0·5 &quot;</td>
<td>61·5</td>
<td>61·9</td>
<td>11·9</td>
</tr>
</tbody>
</table>

I have also tested the behaviour of formaldehyde, which, under the name of formalin, is being introduced as a preservative, and is therefore likely to be present in food stuffs required to be digested. According to Loew (J. Prakt. Chem., [2], xxxvii., 101) formaldehyde at 40° renders diastase inactive. With papain it has an arresting effect, thus:—

<table>
<thead>
<tr>
<th>Percentage Undigested in Presence of Solution of Formaldehyde</th>
<th>0·01 p.c.</th>
<th>0·1 p.c.</th>
<th>1·0 p.c.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Strength of Acid</td>
<td>78·8</td>
<td>83·1</td>
<td></td>
</tr>
</tbody>
</table>

Papain can therefore be used as a digestive ferment in acid, alkaline and neutral solutions. Its activity is diminished at temperatures above 40° C., and is most pronounced in the presence of small quantities of liquid. No appreciable advantage is gained by using a larger amount than one per cent. by weight of the proteid in its natural state. Its activity is most pronounced in the presence of a hydrochloric acid solution of about 5 per cent. strength, whilst for alkaline digestion a 5 per cent. solution of sodium bicarbonate gives the most satisfactory results. After from three to four hours the rate of digestion becomes very slow, so that for practical purposes this length of time is to be recommended.
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS.

In a set of experiments, using 15 grammes of coagulated egg albumin—equivalent to 2.267 grammes of dry albumin, and containing 340 grammes of nitrogen—under the condition of nitrogen rendered soluble in three hours by 0.15 grammes papain in the presence of (1) 45 C. c. of 0.5 per cent. hydrochloric acid, (2) 45 C. c. of 0.5 per cent. sodium bicarbonate solution, and (3) 45 C. c. of water, were as follows:—

HCL NaHCO₃ Water.

Wt. nitrogen in grammes 0.193 0.121 0.0998
Percentage of soluble nitrogen 57.0 35.6 29.3

It seemed of interest to compare the action of papain with that of papain under the conditions which are favourable to the action of papain, viz., in the presence of a small amount of liquid. For this purpose two samples of papain were employed, and the amount of digested mince meat fibrin and egg albumin both determined. The following results were obtained:

1. Meat fibrin quantities.

Weight digested.

- Meat fibrin 10 grammes
- Ferment 0.1 gram
- Distilled water 30 C. c.
- Time 30 minutes
- Temperature 38° C.

Papain, P.D.
Papain, H.S. Papain, P.I.
A. 12.18 per cent. 11.82 15.34
B. 20.9 17.2 41.1

2. Egg albumin. Weight digested.

Conditions the same with constant shaking.

Papain, P.P. Papain, H.S. Papain, P.I.
A. 20.16 20.84 20.42
B. 14.0 14.7 14.5

Under these conditions the papain gave the best results with meat fibrin, whilst with egg albumin the amount of digestion was intermediate between that given by the two papains examined.

From an examination of the products of digestion in one experiment in which the total nitrogen digested amounted to 0.105 grammes, I found it distributed as follows:

<table>
<thead>
<tr>
<th>Coagulable albumin</th>
<th>0.0253</th>
</tr>
</thead>
<tbody>
<tr>
<td>Albumoses</td>
<td>0.0268</td>
</tr>
<tr>
<td>Peptone</td>
<td>0.0268</td>
</tr>
</tbody>
</table>

Total 0.1049

The President said this paper would no doubt prove of great value. Personally he had no experience of the digestive action of papain.

Mr. Reynolds said, although he could quite understand the author was not likely to introduce clinical matter into the paper itself, he would recognise that pharmacists felt considerable interest in the application of remedies, and that pharmacists only was a means to an end. Papain had been recommended as a solvent for the diphtheritic membrane, and it would be interesting to know if that was likely to prove correct.

Mr. Unney said it was unfortunate that two noted pharmacists who had worked on the subject, Mr. Bengough and Mr. Dott, were not present. There had been many conflicting statements with regard to papain, and if he remembered aright, Mr. Dott said that papain had only a slight solvent action at the temperature of the body, and practically no peptonising power. He should be glad to know if Dr. Ridelal confirmed this or disagreed with him.

The President said one point which must strike everyone as very remarkable with regard to these ferments was the small percentage which appeared to be active, and the great activity it possessed. When they had a preparation of papain of 1 in 100 it was thought to be active, but some now they had, 1 in 4000 which was active, it suggested itself to him whether there might not be something similar in the action of these unorganised ferments to what was known as catalysis in chemistry, where a small amount of one body, not altered in itself, practically acted as a carrier and altered the substances which it attacked. There were evidently a number of problems suggested by this paper.

Dr. Rideal said he was not a medical man, and therefore could not deal with the question put by Mr. Reynolds. With regard to Mr. Unney's question as to the discrepancy between Mr. Dott's work and this, it depended entirely on the conditions. Most previous investigators as far as he could remember, had had that papain was something like peptic, and followed the peptic directions. They got results which were contrary to the results shown in this paper, but if they followed the conditions he laid down, they would get good results. The conditions were altogether different from those of papain. The offshoot of the fluid, keeping the fluid down, you got good results with papain, but if you had present a large quantity of fluid, papain was the best and papain the worst.

The Conference here adjourned for luncheon. On resuming, the following note was read:

NOTE ON COCO-NUT STEARIN AS A BASIS FOR SUPPOSITORIES.

BY C. J. S. THOMPSON.

Some years ago several experiments were made with a view to utilising coco-nut stearin as a basis for suppositories and pastes, but lack of time prevented the complete report being given. The report shall be finished when the subject is attacked in the course of many recent years. A sample of the base was discovered, prepared at that time and still in excellent condition.

The suggestion is by no means a new one, as Brady, in a paper read before the Pharmaceutical Society in 1866 on "Medicinal Pessaries and Suppositories," drew attention to the fact that a satisfactory base for suppositories could be prepared from coco-nut stearin.

For this purpose he recommended the following formula:

- Coco-nut stearin 9 cts.
- Lard 1 cts.
- Oil of pimento 20 minims.

The essential oil was added to prevent rancidity, and the lard as a tempering medium. This base, the author states "will keep unchanged for any reasonable length of time, and leaves little to be desired."

From my own experience with the base it was found much too soft, as it melts at 82° F., and the product when set will scarcely bear handling.

The coco-nut oil of commerce, with which you are all familiar, is the fixed oil of the Cocos nucifera, usually obtained by expression.

When pure it should be of a fine white colour, about the consistency of lard at ordinary temperatures, becoming solid at 40° or 50° F., and having a melting point of about 80° F.

It has a bland taste, and its pleasant characteristic odour is well known.

Most authorities now agree that it mainly consists of a peculiar fatty principle called cocin in, with small amounts of olein.

Cocin, when saponified with alkalies yields glycerin and cocostearic acid, the formula being given as C₃₁H₅₁O₂₂. According to Allen, the main constituent is the glyceride of lauric acid, C₁₇H₃₃O₂, and the glycerides of myristic, palmitic, and stearic acids are also present in notable quantities. It is readily soluble in alcohol, and has been also found to contain capric,
caprylic, capric, and other volatile acids. Its tendency to become rancid is small, and on account of its ready absorption when rubbed on the surface of the body it is largely used in Germany as an ointment base, and in this country in the massage treatment.

It is further claimed to be less liable to produce chemical changes in the substances with which it is associated than lard, and also preserves them better than the animal fat.

The 'United States Dispensatory' states the ointment of iodide of potassium, when made with lard, becomes yellow in a few days, while if made with coco-nut oil remains unchanged for two months or more.

The melting point of coco-nut stearin being low, in order to form a satisfactory base for suppository, the addition of some more solid body is necessary, and for this purpose after experimenting with several substances I have found white wax answer the purpose best.

The following formula gives a satisfactory result:—

Coco-nut stearin .......................... 4 ozs.
White wax .................................. 340 grs.
Melt together in a gentle heat over a water-bath.

The product is of a firm and fairly hard consistence, with a melting point of about 86° F., becoming solid at 64° F., and will be found admirably adapted for a suppository base. The melting point if considered too high may easily be lowered by using less wax. It mixes well with vegetable extracts, does not go soft on standing, does not become rancid when in contact with metallic salts, and cools more rapidly than coco-butter.

Coco-butter is now so generally used, and so admirably answers the purpose of a suppository base in almost every respect, that it is a difficult matter to suggest a rival or a body more suitable.

From a pharmaceutical point of view I have found the coco-nut stearin base answer equally well. It has the further advantage of being cheaper, and can be made at a third the cost of coco-butter. It cools very rapidly, and at ordinary temperatures is set and ready to be taken from the mould in about ten minutes.

Suppositories have been prepared with this base from all the B.P. formulas, also with belladonna, h Mannamellar, carbolic acid, boric acid, and many combinations, and in each case it has proved most satisfactory.

Two medical practitioners, who kindly undertook experiments with both suppositories and resins prepared with the proposed base, report as follows:—

"The result has in each case been satisfactory and rapid, showing that they have been readily absorbed. As regards the suppositories themselves, they appear to be excellent, and have a very good appearance."

The President said he was very sorry the author was not present. He supposed the justification for this paper was to be found in a paragraph in the last edition of Squire's 'Companion to the Pharmaceutical Journal,' where it was stated that coco-nut stearin was, as a basis, better suited for suppositories in cold weather. As already mentioned, Mr. Brady, in 1865 and 1866, made a number of experiments, and he quoted the formula Mr. Brady said might be used. Since that coco-butter had been used, and was absolutely indelible, and had he yet to learn that the internal temperature of the body varied in summer and winter. He had tried an experiment since the paper was put on the list, and found, after surrounding coco-butter suppositories with ice for twenty-four hours, that the time during which they would melt in water of the temperature of the human body was not materially altered, even by the fraction of a second, from those made in the ordinary way. The possibility was that the oxidation of the surface of the coco-butter, which went on by keeping suppositories, might retard to a slight extent the time during which they would melt. But coco-butter was simply an ideal basis for suppositories, and absolutely fulfills all the conditions. It did not become rancid. It did not change by keeping, and it could be handled at practically any temperature of the English climate, and introduced safely. Stearin suppositories, if made, must be made to suit the temperature, which would vary between winter and summer, and the suppositories made in January would find the mere handling of them would render them too soft to be used properly. To introduce a suppository required a little pressure; you must have sufficient firmness, but when it is, it dissolved at the temperature of the body, which was practically the same, summer or winter. Since the publication of Mr. Brady's papers in 1866, the only change that had been suggested was that in sending suppositories to India, where morphine suppositories were of great value for dysentery, a little wax was added to raise the temperature at which they would soften. Something was wanted about the character. He was certainly in favor of economy avoiding waste—but cheapness had nothing whatever to do with pharmacy. Who would go into the fractions of decimals that would show the difference between twelve stearin suppositories and twelve made with coco-butter? It was absolutely ridiculous. This reference to economy occurred in three or four papers, but it was absolutely beside the question. Coco-butter answered every requisite. Mr. Brady showed that at that time the German was better than the French, and the French better than the English, but since then English coco-butter could be obtained by the ton at a few pence per pound, absolutely pure. As he had said, the paper might be justified by the paragraph in Squire's book, but he was sorry to see any suggestion that the basis in the B.P. should be altered. That morning there was a question about stearic acid being cheaper than oleic acid, but you could not get any definite body called stearic acid, though you could get coco-butter, which was practically always alike, and did not vary materially in its melting point, and would keep practically for ever.

Mr. Gerhard said up to the present time there had never yet been presented a suppository base that was equal to coco-butter. On one point, perhaps, he might differ from the President, who said that coco-butter did not become rancid. His experience was that it did become rancid, and lost its yellow colour, which was evidence of it. A piece of coco-butter placed in a glass bottle, as was often done in museums, and exposed to light and air, would give evidence of rancidity in the course of two or three months, the colour being changed from yellow to white. It would be very strange if a natural fat did not become rancid. It was true that as compared with other fats it was not so prone to rancidity and was not offensive. About twelve months ago his attention was called to a coco-butter made by a London confectioner, who sold it in large confectioners. He told him it was called coco butter, and was sold under that name. It was a beautiful yellow butter, exactly like the ordinary coco-butter, very different from the sample now produced, and had an aromatic odour. His friend said it was made from coco-butter and some other substance, to impart to it a slightly greasy character to prevent it adhering to the mould. He gave him four or five pounds to experiment with, and after testing its qualities he came to the same conclusion as the President, that this coco-nut stearin was not equal to coco-butter as a suppository base.

Mr. Martindale agreed with the President that thebeoroma was an ideal substance for suppositories. The sample of stearin sent round was very nice.
but the disagreeable odour it assumed when it became rancid made it very objectionable. Theobroma if it ever became slightly rancid was never disagreeable.

Mr. Unsworth said his experience was not quite so great as that of the President or Mr. Gerrard, but he quite agreed with the last speaker that in cocoa butter they had a thoroughly sound basis for supposititions.

Time was when that substance could not be obtained in a pure condition, but public taste had advanced since then, and now the united makers of cocoa without fat sent on to the London drug market a constantly increasing quantity of genuine cocoa butter in a natural condition, and it was also largely supplied blessed. Every two or three months a quantity such as 100 toses would be offered by public auction. As the President had said, a substance could be obtained which varied only within a few degrees of melting-point, and his own impression was that there ought not to be a greater difference allowed. Unfortunately, the Pharmacopoeia gave a larger latitude, and he feared that such encouraged sophistication. He thought one degree from either side of the exact melting-point of pure cocoa butter would be quite sufficient.

Mr. Martin said the great point was to be sure it was dehydrated.

The President said cocoa butter could be got in any quantity, and apparently a great deal of it was imported, but in twenty years' experience he had never found any difficulty in getting any quantity of it at a moderate price which would melt at a difference of between one and two degrees. Of course it would oxidise, but did not become rancid in the sense that sterin would—in the sense of producing irritating acids which would make it inapplicable in the case of a sensitive rectum. It became rancid probably in a purely chemical sense, but after the suppository had been made for twelve months or two years, it was quite safe to use. If one could find a basis which was superior, by all means substitute it, but if not, there was no reason for dissatisfaction.

(To be continued.)

Parliamentary and Law Proceedings.

POISONING CASES AND INQUESTS.

POISONING BY PHOSPHIC ACID.

On Friday, August 10, Mr. John Henry Negus, aged 28, pharmaceutical chemist, of Gold Street, Northampton, was found by his sisters dead in his bed. At the inquest held by Mr. C. C. Buckle, the borough coroner, Mr. Lee F. Cogan, surgeon, stated that he was called to see the deceased about a quarter to three o'clock the previous afternoon. He was then lying on a bed, dead, in his bedroom. Witness gave some of the brain of the deceased, and was shown a bottle containing phosphic acid, from which about 20 minims was missing. That was quite enough to cause the death of a man. The symptoms of the body were such as to lead witness to believe death had been caused by phosphic acid. Witness had made a post mortem examination of the body, by order of the coroner, the result of which was that he attributed the death of the deceased to the taking of phosphic acid. All the organs were healthy except the lungs. Witness had known the deceased for some time, and had attended him; and he knew him to be a very nervous man, and given to fits of derangement. The cause of death summed up the evidence, the jury returned a verdict of "Suicide whilst temporarily insane."—Northampton Daily Chronicle.

DISPENDING AT HOSPITAL.

On August 3, at Guy's Hospital, Mr. Arthur Langham, deputy coroner for Southwark, held an inquest on the body of a deceased male of a melancholy and a half of chloral, which prescription was written down and handed to the nurse to make up and administer. At twenty minutes to twelve he was summoned to the deceased, and learned that the nurse had mistaken the sign in the prescription and administered an ounce and a half of a calomel and a half of a half ounce, and although emetics were immediately given, the patient's death occurred early in the morning. Nurse Emily Margaret Fox, in charge of the John Ward, who was previously cautioned by the coroner, deposed that the deceased was under her care. The Coroner: Did you carry out these directions, or not? No. The Coroner: What did you give him? I mistook the sign of a dram for an ounce. Witness added that she discovered her mistake five minutes afterwards, and she at once sent for the house physician and the clinical assistant. After further evidence, the coroner summed up, and the jury at once returned a verdict of accidental death.—Daily Chronicle.

SUICIDE BY CARBOLIC ACID.

The Manchester deputy city coroner (Mr. S. Smelt) held an inquest on Monday, August 6, on the body of Samuel Goodlad, aged 34, of Booth Street, Hulme. On Saturday the deceased went home under the influence of drink, and whilst standing in front of the kitchen fire he took a small bottle from his pocket and drank the contents. In reply to his wife he stated that he had taken something for his head. A doctor was called in, but deceased expired on Sunday. A young man named William Sanders stated that he was an assistant to Messrs. Hargreaves and Sanders, chemists, of Booth Street, Hulme. On Saturday deceased called at the shop and asked for twopennyworth of carbolic acid to kill some vermin. He was supplied with both carbolic acid, "poison." He told deceased to be careful as it was a deadly poison, and he said he would see to it. In answer to the coroner, Sanders stated that he took a rough look at the deceased, and he did not think he was in drink. Mr. Smelt said that a chemist ought to be sure when he sold a poison to anyone. In answer to a jurymen, the coroner said that Sanders had no right to sell a poison, as he was an unqualified assistant. The jury returned a verdict that deceased committed suicide whilst drunk, and at the suggestion of the jury Mr. Smelt said he would communicate with the Pharmaceutical Society.—South Manchester Chronicle.

ACCIDENTAL POISONING BY ATROPINE.

At the Oldham Workhouse Infirmary, on Thursday, August 9, an aged woman, named Ellen Rattcliffe, died in one of these wards under sad circumstances, and an inquest was held at the workhouse this afternoon, before Dr. George Thomson. The deceased had been in a dangerous condition for some time, and on the Wednesday night the night nurse (Nurse Wallis) had in the course of her duty to administer a dose of whisky to the patient. She unfortunately appeared to have mistaken the bottle, and instead of giving her a dose of whisky, as she intended to do, she gave her a dose of poison, called atropine, and the woman died shortly afterwards. After hearing the evidence, the Coroner said it was patent that Nurse Wallis had been
responsible for the unfortunate error. They could only look upon it as one of those strange errors of judgment which people sometimes made, and had the nurse been under ordinary conditions he was not sure that it would not have been necessary to return a verdict of "misadventure." Encouraged by the reports to the contrary, and feeling that a verdict of "misadventure" would be the right one, a matter which must have struck the jury was that a deadly poison like atropine should have been placed in a similar bottle to that containing whisky, and in the same cupboard. It was usual in infirmaries to have poison in bottles thoroughly dissimilar from those containing medicines for internal administration, and it was curious that that had not been done in this case. The jury returned a verdict of "Death from Misadventure," with a recommendation that in the future poisons should not be kept in bottles similar to those containing medicines for internal administration, and they also recommended the guardians to increase the nursing staff for night work.
—Manchester Courier.

POISONING BY LABURNUM SEEDS.

A boy, named Alexander Stoddart Affleck, aged 2 years and 6 months, died at the Boundary, near Penicuik, Midlothian, on Monday, August 20, from eating the seeds of Cytisus laburnum. There seems no doubt that he ate the seeds; he afterwards complained of sickness, and was later seized with violent purging and vomiting of green matter. Dr. Badger and Dr. Paterson of Penicuik, were called in, and an operation was unsuccessfully tried, and then purgatives, but they were too late, and the child died, having been in severe pain all along, after passing into a state of coma. Several poisoning cases from a similar cause occur in this locality every year, but are generally caught in time, and the victims are saved. Ten cattle belonging to a gentleman in the neighbourhood recently showed severe symptoms of poisoning, which were traced to several laburnum trees growing in the park, and their timely removal put an end to the danger, which nearly produced fatal results.

PROCEEDINGS UNDER THE PHARMACY ACTS.

ACTION AGAINST AN UNREGISTERED PERSON.

At the Gloucester County Court, on Tuesday, before his Honour Judge Elliscott, an action was brought on behalf of the Council of the Pharmaceutical Society of Great Britain, by Mr. Richard Brammidge, the Registrar of the said Society, against William O. Davis, carrying on business at Northgate Street, Gloucester, as the City Drug Stores, to recover the sum of £5, the amount of a penalty incurred by him on May 15, 1894, for selling a poison, or wit, "arsenic," contained in a compound called "Cooper's Sheep Dipping Powder," or a preparation of arsenic called "Cooper's Sheep Dipping Powder," contrary to the provisions of the Pharmacy Act, 1868 (31 and 32 Vic., cap. 121); also to recover the penalty incurred on May 16, 1894, for selling a poison, to wit, "arsenic," contained in a compound called "Cooper's Sheep Dipping Powder," or a "preparation of arsenic" called "Cooper's Sheep Dipping Powder," contrary to the provisions of the said Act: also to recover the penalty of £5 incurred by defendant on May 16, in taking, using, or exhibiting the name or title of "chemist" contrary to the provisions of the said Statute.

R. Vaughan Williams (instructed by Messrs. Flux, Thompson and Flux of London) appeared on behalf of the Society, and Mr. W. Langley Smith, solicitor, Gloucester, defended.

In opening the case for the Society, Mr. Vaughan Williams stated that the defendant had been trading as W. Davis and Co., and the action was to recover three penalties under the Pharmacy Acts, under circumstances set forth above. The facts of the case were as follows. On May 7 last Mr. George Pidlaye went to the shop of W. Davis and Co., 52, Northgate Street, Gloucester, and purchased a packet of "Cooper's Sheep Dipping Powder," which he paid for by the defendant himself, and the penalty to be recovered was £5. There was also an action in respect to the defendant keeping open shop for selling, using, and exhibiting such articles, which contained poison. On May 16 Mr. Pidlaye again went to defendant's shop and purchased another packet of "Cooper's Sheep Dipping Powder," when he was again served by the defendant, while he also purchased two boxes of Vermine's rhubarb pills, which were handed to him in a wrapper. The pills were "Professor Verme's celebrated rhubarb pills," as the wrapper stated, and were sold by Mr. William Davis and Co., 52, Northgate Street, Gloucester." The packets containing the sheep dip were kept by Mr. Pidlaye, and were subsequently handed over to him by Mr. Moon, clerk to the Registrar of the Society, who afterwards handed them over to Mr. Beate, analyst to the Society. Mr. Vaughan Williams then proceeded to call attention to the various Acts of Parliament bearing upon the question of persons dealing in poisons contrary to such Acts, and by so doing rendering themselves liable to certain penalties. Section 15 of the Act of 1868 provided that the 31st December, 1868, was the penalty for keeping open shop for retailing poisons, or who should use the name of a chemist or druggist, for every such offence was liable to a penalty of £5. The defendant's name did not appear on the Register of Chemists and Druggists, and he was therefore liable to a further penalty for styling himself chemist. The sheep dip which the defendant sold to Mr. Pidlaye contained a large quantity of arsenic, in fact the amount was sufficient to poison a number of persons. It was one of those drugs which were specially dealt with by the Legislature and a poison which was to be sold only by qualified chemists, and to persons who might be introduced to the person by someone who was a chemist. The Society took up these cases in the interest of the public; there was no personal feeling whatever in the matter against the defendant, but the Society felt bound to take the present proceedings against the defendant.

The first witness called was George Pidlaye, who said he resided in Cheltenham. On May 7 last he went to Davis's shop in Northgate Street, which he took to be a chemist's shop. He purchased a packet of "Cooper's Sheep Dipping Powder," for which he paid 1s. He asked defendant for his name after he purchased the powder, and defendant gave him an adhesive label, which witness placed on the packet after he got home. He went to defendant's shop again on May 16, when he purchased another packet of sheep dip, the two packets of which he now produced. He was served by defendant on that occasion, as he was on the previous occasion. On May 16 these two packets of sheep dip and a large quantity of rhubarb pills, which were wrapped in a printed circular, on which were the words: — "Sold by W. Davis and Co., chemists, etc." Witness kept the packets of sheep dip and also the handbill till he handed them over to Mr. Moon, the clerk to the Registrar of the Society. The name over the shop window was that of "W. Davis and Co., the City Drug Stores."
Cross-examined by Mr. Langley Smith, witness said he was an agent to the Society and resided at Cheltenham. He was requested to go to the defendant's shop by the Society. He did not know whether any previous information had been given. He was told to go to the defendant's shop to sample of the poison. His experience in such business was not very great. He did not know whether there was any difficulty in getting these packets of sheep dip at any other shop in the city.

Mr. Vaughan Williams objected to the question, as he said it was not evidence.

Cross-examination continued: Witness said he could not say the powder was composed of arsenic, as he was only asked to get a packet of the dip. He did not know it was composed of arsenic nor that under section 17 of the Act of 1868 the packet ought to have a label stating that it was a preparation of poison.

Mr. Langley Smith: Did you not think the Society ought to prosecute the makers of the sheep dip, and not the retailers?—I do not know. I do not know what the powder is used for, as I was only asked to purchase it. I will swear that the defendant gave me the label. I do not believe I got it from the packets because I should be less liable to lose them. I have only been on one prosecution before. I have resided in Cheltenham for about twelve months, previous to which I resided at Weston-super-Mare. I made a note of my visit to defendant's shop after I got home, and sent it up to the Society.

By Mr. Vaughan Williams: I am an agent employed by the Society to make inquiries.

The label on the sheep dip packets was then read, which was to the effect that it was a preparation of poison.

Mr. Harry Moon, clerk to the Registrar of the Pharmaceutical Society, said he received the two packets produced, with a report from the last witness, and handed them to Mr. Essets, the analyst. They were handed to witness on July 20. When he received the packets they had not been opened. He handed them to Mr. Essets on August 27. He thought it was possible to see the word "poison" on the packets.

In answer to Mr. Vaughan Williams, witness said that from the time he received the packets to the time he handed them to Mr. Essets they were closed. It was impossible for the contents to have been taken out if they were locked up.

Mr. Ernest John Essets said he was an analyst, a Fellow of the Institute of Chemistry demonstrator to the Pharmaceutical Society, and assistant to Professor Attfield. He had had considerable experience as an analyst for a great many years. He received the packets of sheep dip produced, at which time they were enclosed. He analysed them, and found the dip to consist of arsenic, sulphide of arsenic, and sulphur. The total weight in each packet was nearly 2lbs., about one-third sulphur, but the greater portion was sulphide of arsenic, with a quantity of free arsenic. Arsenic was a very dangerous poison, and should only be sold by persons duly qualified, to persons who were well-known to them, whose signatures should be entered in a book kept by the chemist for that purpose. There were nearly 2000 grains of arsenic in each packet, and one packet would be sufficient to poison hundreds of persons.

By Mr. Langley Smith: There was a register of chemists kept. He did not know that the dip was sold by grocers. He had never purchased any. If there was only a very small quantity of arsenic it would come within the provisions of the Act. There was nothing on the outside of the packets to indicate that they contained arsenic, but only the word poison.

In answer to Mr. Vaughan Williams witness said the law requested that poison registers should be kept by chemists. He had known of cases where penalties had been enforced where the contents included only 1/10th of a grain of poison. There was a very large quantity of poison in the packets produced, in addition to sulphide of arsenic.

Mr. Vaughan Williams hero put in the register of the Society to prove that the defendant's name was not entered in it.

Mr. Langley Smith said he was quite willing to admit that the defendant's name was not on the register. He went on to say that he considered it a very cruel action on the part of the Society, as they were not content to proceed with one case only, but proceeded with three. According to the Act of Parliament it was really a persecution of the poor man. He was only keeping what many hundreds of persons in England kept, a drug store, and amongst other articles sold was sheep-dipping powder. He could prove that the packets could be purchased at any grocer's shop in the city, and he produced a packet which his clerk had purchased the day before. The defendant did not know that he was doing wrong, and he did not know that he was committing any offence when he sold the powder.

He (Mr. Langley Smith) thought the Society ought to go to the fountain-head and prosecute Cooper. But they did nothing of the kind. The upset of it was that his client obtained the powder from chemists in the city, and when it was asked for he simply handed it over the counter. It was an innocent act on the part of his client. He submitted he was not retailing a poison, and that arsenic was not one of the poisons mentioned under the Act.

The Judge: Can you refer me to any case where a guilty knowledge must be proved under the Act?

Mr. Langley Smith: Perhaps not, your Honour.

The Judge: Then you want to bring in a guilty knowledge?

Mr. Langley Smith: Yes.

The Judge: But it is not in the Act.

Mr. Langley Smith asked his Honour whether it would not constitute one offence only, and that the sum recoverable was £25? It was surely one and the same offence, as it was dealing with the same powder.

The Judge ruled that there were three different offences, and that the Society was entitled to the amounts sued for, and he gave judgment accordingly.

As to the question of costs, Mr. Vaughan Williams applied for an order for £1 a month.

Mr. Langley Smith asked his Honour not to allow costs. He called the defendant, who stated that he only got a profit of a penny upon a packet of sheep dip. He kept a ledger who paid him 12s. a week. He had a wife and two young children, one of whom was only six months old. He could not offer more than 10s. a month for the costs.

Mr. Vaughan Williams said his takings were £4 a week, and his profits were about a third on an average.

His Honour then entered judgment for £15, and made an order for the costs to be paid at the rate of 10s. a month.

Obituary.

Notice has been received of the death of the following:

On August 4, Joseph Parkes, Pharmaceutical Chemist, Atherstone. (Aged 72.)

On August 7, William Samuel Weeding, Chemist and Druggist, late of Walworth. (Aged 40.)
Correspondence.

The Dose of Ancyramidide.

Sir,—There is an interest for dispensers as well as for prescribers in the report of the Therapeutic Committee of the British Medical Association just presented to the Annual Meeting. The point of interest to me, however, is one of the simplest and most important in the authoritative expression of opinion by the Therapeutic Committee (of which Professor Leech, of Owans College, is Chairman) that the proper dosage of a chemico (antifibrin) is from one to four grains. The majority of practitioners, who are supposed to have learned to count from four to ten grains, may shield themselves under the official dose given by the B.P., Appendix, 1890, viz., "three to ten grains," a fact which is rather singularly ignored by the Therapeutic Committee. For future prescriptions, there can be little doubt that prescribers will accept the new dosage of this drug, and it is desirable that dispensers also should be aware of the circumstances that will have decided the change.

R. REYNOLDS.

The Revision of the British Pharmacopoeia.

Sir,—In revising the present B.P. I think a slight alteration might be made in the recipe for tinct. benzoin. Instead of rectified spirit one pint, it would be better to read rectified spirit a sufficiency. In the directions for making it, it says macerate for seven days, filter, and add rectified spirit, if required, to make one pint. The original recipe states that "after it is finished it measures exactly 15 ozs. over the original six pints, which is equivalent to 24 ozs. per pint." Of course this might not work out exactly the same in making one pint, as the loss filtering would be more in proportion. Another alteration I believe would be beneficial in making syrups, B.P. Whilst recognising the fact of keeping the syrup up to a certain density to prevent fermentation, a small amount of water is substituted for part of the sugar would prevent the syrup crystallising, and at the same time keep up the density.

Cambridge.

H. T. PARKER.
Aids to Aseptic Surgery.*

BY EDMUND WHITE, B.SC. LOND., F.I.C.,
Pharmacist to St. Thomas's Hospital.

STERILIZED SURGICAL DRESSINGS.

The supply of sterilised dressings to a large institution presents a number of difficulties which are not encountered in private surgical practice. I propose to give an account of the apparatus and method of procedure which have been adopted in St. Thomas's Hospital.

The steriliser, Fig. 1, is a cast-iron circular vessel, having an internal diameter of two feet four inches, and a depth of two feet. The walls are \( \frac{3}{4} \) -inch thick, and are covered to a thickness of two inches with asbestos to prevent loss of heat as much as possible. The lid is flat, \( \frac{3}{4} \) -inch thin, and strengthened by four radial ribs. It is secured in place by six swivel bolts, four of which are shown in the figure, and raised by a wheel and screw, \( H \), passing through an arm or davit. This davit turns

\[ \text{FIG. 1.} \]

Apparatus for rendering surgical dressings aseptic.

in the two sockets, \( F, G \), thus allowing the lid to be swung aside when raised. Inside there are two removable shelves of perforated galvanised iron, supported by projections cast on the interior of the steriliser. The steam supplied from the boiler of the pharmaceutical laboratory enters at the side through the pipe \( A \), waste steam and condensed water escape through the pipe \( B \). A safety-valve, \( C \), and pressure gauge, \( D \), complete the apparatus.

The dressings are cut, folded, or made into the form in which they will be used, and placed into cylindrical glass jars provided with flat overlapping lids. The size most often used is eight inches in height and four inches in diameter.

\[ \text{FIG. 2.} \]

Temperature regulator for use in sterilising water. The jars are filled by the "sister" who has charge of the case for which the dressings are intended. They are placed in the steriliser lying on their sides with the lids off, and exposed to the action of steam for one hour. The steam pressure is allowed to rise gradually during the first fifteen minutes until the gauge shows 18-20 lbs. to the square inch, a pressure corresponding to a temperature of about 125° C. At the expiration of the hour the supply of steam is shut off and the compressed steam allowed to escape by opening the tap in the pipe \( z \). The lid is released by unscrewing the swivel bolts, and raised about half an inch to allow the remaining steam to diffuse out. It is next swung aside and the jars removed by an attendant, who spreads over the mouth of each a layer of sterilised cotton wool before putting on the lids. The layers of wool being compressed between the edge of the jar and the lid prevents the ingress of dust or germs. Over each jar a long, narrow label, gummed at the ends, is placed, on which is marked the ward from which

* By the courtesy of the editors of the forthcoming volume of the St. Thomas's Hospital Reports, we are enabled to reprint this article from advance sheets.—[Ed. F. J.]

Vol. LIV. (Third series, vol. XXV.), No. 1263.
and secure a thoroughly moist atmosphere, and for the rest of the time the tap in the pipe is kept slightly open, just enough to allow the condensed water to escape with a little steam.

**STERILISED WATER.**

The apparatus for the supply of sterilised water for irrigation, etc., in surgical operations consists of two parts, the first, Fig. 2, in which water supplied from the mains is brought to the required temperature, and the second, Fig. 3, in which the water is sterilised by passage through a Bessefeld (kieselguhr) filter.

Fig. 2 consists of an outer copper cylinder, nine inches long and three inches in diameter, in which is placed a coil of copper tubing thickly tinned inside. Through this coil water passes from the hot water main, and its temperature is recorded by the thermometer T. As this is nearly always hotter than required, the space around the coil is filled with cold water entering through the tube C. By means of the tap D at the bottom the outflow of this cold water may be so regulated as to bring the water leaving the coil to the desired temperature. The water then passes to the filter through rubber tubing sufficiently long to allow the filter to be moved easily to any part of the operating room.

The filter, Fig. 3, which is twelve inches long by about three inches in diameter (outside measurement), consists of a cylinder of compressed kieselguhr enclosed in an iron jacket. In the figure the position of the filtering cylinder is indicated by the dotted lines. The water entering at A fills the space between the jacket and the cylinder; it is driven through the latter, and escapes sterilised by the tube B. The filter is mounted on an iron tripod, provided with rubber-tired wheels to enable it to be easily moved about the operating table. With twelve feet of tubing between the coil and filter it is found that the temperature of the water passing from the thermometer T, Fig. 2, to the orifice of A, Fig. 3, falls from 2°C to 5°C. That is, if water at 100°C is required, the thermometer should indicate 102°C—105°C.

When hot water is not available the coil may be used thus:—Cold water is passed through the coil, the space outside being also filled with cold water. A gas burner placed beneath the cylinder heats the water around the coil, the water passing through being brought to the desired temperature either by regulating the gas burner or by opening the tap D.

In places where the pressure in the hot and cold water pipes is the same, the waters may be mixed, before entering the coil, in the proportion to give the desired temperature. Regulation of temperature by the flow of cold water through C to D, Fig. 2, is then unnecessary. It is advisable even in this case to have the coil arranged as shown, for in case of failure of the hot water supply, gas may be used as the source of heat.

The sterilising power of the filter has been tested at the end of one hour, twenty-four hours, and forty-eight hours' continuous passage of water. In no case could any growth be obtained by inoculating culture tubes, either at ordinary temperature or at 40°C.

It is advisable to remove the kieselguhr block, boil it in water about every other day, and lightly brush it in order to remove the deposit which collects on the outside and retards the flow of water through the filter.

---

**THE CULTIVATION OF LIQUIORICE.**

The liquorice plant (**Glycyrrhiza glabra**, L.) is a native of North Africa, Southern Europe, Syria, Persia, and Afghanistan, and is cultivated in France, Russia, Germany, Spain, and China, and also to a slight extent in England, where its growth is said to date from the middle of the sixteenth century. Some twenty or thirty years ago liquorice was cultivated in market gardens in the neighbourhood of London, especially about Kew and Isleworth, and more recently at Mitcham. At the present time Yorkshire produces the larger quantity of English-grown root, and the principal seat of its culture is in and around Pontefract. Its cultivation in this particular neighbourhood dates back several generations, the deep, rich, loamy soil which occurs here being specially suited to the growth of the plant. The bulk of the liquorice gardens are situated on the fertile slopes east and north-east of the town, the country between Pontefract and Knottingley being largely occupied by market gardens, in which liquorice forms an extensive crop.

The following notes on the cultivation of the plant and harvesting the root are taken from an article on the "Culture and Preparation of Liquorice," which appeared in the *Leisure Hour*:

"The plants are grown in rows, and they stand from three to four years before arriving at perfection. The three years' growth is thinner and scarcely so rich in juice as the four years' plants. Occasionally, if the market is flat, the plants are allowed to grow a fifth season, but the root becomes thicker, coarser, and
more woody. The long straight root goes down to a
great depth, averaging perhaps about 4 feet, but
sometimes even to 6 feet; and as the soil has to be
dug down to this depth by hand to extract the root,
the labour of cropping or harvesting is considerable.
During the first two years that the land is occupied
by liquorice, the plants themselves, being small, allow
of other crops being planted between the rows, and
potatoes, and different varieties of cabbage, are mostly
grown. The ground being earthed up around the
liquorice plants, the furrows thus made afford much
protection to the vegetable crops, and as the ground
is always richly manured before planting liquorice,
favourable conditions are thus ensured for the pro-
duction of early and very superior vegetables; indeed
it is said that the vegetable crops from a liquorice
plantation always command high prices in the Leeds
markets. After the second year, however, the liquorice
plants grow to such a height, and spread their foliage
so widely, that other crops will not grow beneath
them. On a visit to Pontefract, namely, in the early
part of September, the writer saw some of these liquorice
gardens where the plants had attained the age of five
years and a height of about 4 feet, each plant send-
ing up numerous straight stout stems from the root-
stock or crown, each stem bearing large spreading
alternate leaves, composed of a number of opposite
leaflets of a bright green colour.

"The harvesting season is about the middle of Sep-
ember, and after the roots have been taken out of the
ground by hand digging, as before mentioned, they are
stored in cool ventilated houses or cellars, usually in
sand, until a favourable opportunity occurs for the
process of dressing, which consists of trimming off all
the fibrous rootlets, buds, and runners or stolons. The
fibrous roots are ground into liquorice powder, which
is used as a medicine, and the buds and runners are
carefully preserved in sand for planting, for it is from
these alone that new plants are raised, and never from
seed. The plants never being allowed to flower, do
not of course produce seed. Flowering would de-
teriorate the value of the plant from a commercial point
of view, as the juices would be consumed in perfecting
the flowers, and the roots thus become useless. The
planting of buds and runners for a new crop is done in
the early part of April."

In Bentley and Trimen's 'Medicinal Plants,' vol. ii.,
under plate 74, it is stated that "both Spanish and
Russian liquorice roots are usually imported in bales or
bundles, or rarely, in the case of that portion of the
Spanish variety which is derived from Alicante, loose, or
in bags. The Spanish liquorice root is in straight un-
ppeeded pieces, several feet in length, and varying in
thickness from a quarter of an inch to about 1 inch.
That from Alicante is frequently untrimmed and
dirty in appearance, but that from Tortosa is usually
clean and brighter looking. The Russian liquorice
root, which is imported from Hamburg, is either peeled
or unppeeded. It is in pieces, varying from 12 to 18
inches in length, and from a quarter of an inch to an
inch or more in diameter. Combined with the usual
sweetness of liquorice root, this variety has a feebly
ditter taste.—Low Bulletin.

THE ANALYSIS OF MALT.*

BY JOHN A. MILLER, PH.D.

Having been called upon during the past few years to
assay a great many samples of malt, I have been struck
by the variation which existed between the results of
my own analyses and those made by other chemists
upon the same samples. The variations in some cases
were too large to be placed within the possibility of
experimental error. With the belief that these vari-
ations might, in part at least, be due to a greater or
lesser degree of accuracy in the methods employed in
the analysis of malt, I undertook a comparative in-
vestigation of three methods which are quite univer-
sally used.

From the stand-point of the largest consumers of
malt, the important points to be ascertained by the
analysis of a malt sample are 1, moisture; 2, per-
centage of extract which the malt will yield when
submitted to a miniature mashing process; 3, dis-
sorative power, that is the rapidity with which the
starch contained in the malt is converted into sugar
and dextrin; 4, the percentage of acidity (calculated
as lactic acid) which the wort contains.

It has been claimed by some that the percentage of
sugar formed and the amount of proteids dissolved is
of importance in judging of the character of the malt.
The amount of sugar is of no practical value to the
brewer, as the increase or decrease of the percentage
of that article is entirely dependent upon the manner
in which the malt is handled in the mash tub. The
total nitrogen in the malt wort calculated as proteids
is of little value, since the percentage present in the
finished beer will depend upon so many factors as to
render the first results of comparatively little value.
Amongst the factors which will influence this percent-
age are: Character of the water used in mashing;
the use of a high or low initial mashing temperature;
the length of time the wort is boiled in the kettle;
the amount and character of the hops used; the
character and quantity of yeast used; and the charac-
ter of the fermentation.

The four points mentioned are of about equal im-
portance in the assay of a malt sample. The deter-
mination of moisture shows whether the malt has
been properly dried, and also whether the purchaser
is not paying too high a price for an article which he
can obtain very readily from the city water supply.
The determination of lactic acid is of value from the
fact that it enables one to judge, within reasonable
limits, of the age of the malt under examination.
For example, a sample of malt which is low in mois-
ture and high in lactic acid is an old malt which has
been re-dried to bring down the high percentage of
absorbed moisture. In a first-class sample of malt
the moisture should not run above 5 per cent., and
the lactic acid 0·7 per cent.

Determination of Moisture.—Two methods were in-
vestedigated in order to ascertain their relative accu-
ruacy. In the one method from 2 to 4 grammes of
ground malt was used; in the other 20 grammes. In
both cases the samples were heated to 100° C. until

* From the Journal of the American Chemical Society.
the weight was constant. Both methods gave results agreeing to within the third decimal place. The use of from 2 to 4 grammes, however, is to be recommended:

1. Because it admits of the use of ground watch crystals for drying and weighing, thus preventing the absorption of moisture while the sample is cooling.

2. The time required to obtain a constant weight is much less than when 20 grammes are used.

Determination of Extract.—The determination of the percentage of extract which a malt will yield is of very great importance, as upon this percentage the value of the malt largely depends. It is evident that a sample of malt yielding 55 per cent of extract has not the same commercial value as a malt yielding 60 per cent.

METHOD NO. I.

"Fifty grammes of ground malt is weighed out as rapidly as possible (to avoid secession of water) and treated in a weighed beaker with 250 C.c. of warm distilled water, of such a temperature that the initial heat of the mixture may be from 50°-52° C. The beaker containing the mash is placed in a water-bath, and the contents maintained at the same temperature for a quarter of an hour. The heat is then gradually raised till the immersed thermometer registers 59°-60° C., and the temperature is then kept constant till a drop taken from the liquid ceases to give a blue colour with iodine solution and nearly ceases to give a brown. This shows that all the starch and nearly all the erythro-dextrin has suffered hydrolysis—a point which will be reached in about twenty minutes. The heat is then increased to about 70° C. In order to complete the saccharification, when the water in the bath is boiled for five minutes. This step, which completes the process of mashing, should be arrived at in about 100 minutes from the commencement of the operation. The beaker is then cooled and the contents filtered. The insoluble matter is washed with cold water, and the filtrate is made up exactly to 400 C.c. The density of the clear wort is next taken at 15°-5 C. in the usual way by a specific gravity bottle. The excess of density over that of water (taken as 1000) multiplied by 2:078 will give the percentage of dry extract yield by the malt. Instead of ascertaining the gravity of the infusion, the proportion of solid matter may be determined by evaporating a known measure of the wort to dryness in a flat-bottomed dish, so that the residue may form a thin film. The extract dried at 105° C. till constant in weight."

Two portions of 50 grammes each of same sample of malt treated as indicated above gave the following results:

<table>
<thead>
<tr>
<th>I.</th>
<th>II.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specific gravity of the wort</td>
<td>1:0284</td>
</tr>
<tr>
<td>Extract calculated by factor</td>
<td>59:01 p.c.</td>
</tr>
</tbody>
</table>

5:142 grammes of the wort was then taken and placed in a wide flat-bottomed platinum dish and the extract dried at 105° C. to almost constant weight. The following was obtained:

<table>
<thead>
<tr>
<th>I.</th>
<th>II.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weight of the extract</td>
<td>0:3496 grammes</td>
</tr>
<tr>
<td>Average weight</td>
<td>0:3492 grammes</td>
</tr>
<tr>
<td>Percentage of extract</td>
<td>56:67</td>
</tr>
</tbody>
</table>

5:142 grammes was again taken and placed in a flat-bottomed dish, and this in a water oven, the temperature of which was kept at 70°-75° C., and the extract dried to constant weight. The time required for this was about seventy hours.

<table>
<thead>
<tr>
<th>I.</th>
<th>II.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weight of the extract</td>
<td>0:3894 grammes</td>
</tr>
<tr>
<td>Average weight</td>
<td>0:3677 grammes</td>
</tr>
<tr>
<td>Percentage of extract</td>
<td>58 992</td>
</tr>
</tbody>
</table>

METHOD NO. II.

"Fifty grammes of ground malt is carefully weighed as rapidly as possible. The ground malt is put into a copper beaker, the weight of which is known, and this beaker is placed in a water-bath. Water is now mixed with the malt to the amount of 200 C.c., at a temperature of 38° R. This temperature is held while the malt is continuously stirred for thirty minutes, when the temperature is raised to 58° R., 4° R. each five minutes. When the temperature of 68° R. is reached, tests are made in order to find out whether the starch has been converted completely. Usually we find that the temperature of 68° R. has been reached all the starch is converted. The mash is always held thirty minutes after the temperature of 58° R. has been reached, when it is boiled for five minutes, cooled off, and water enough is added to make the weight of the contents of the beaker, or the weight of the entire mash, 350 grammes. The wort is then filtered off. After the wort has been filtered the specific gravity is taken from which the per cent. Balling is ascertained, and the amount of extract in the malt computed to the following formula; viz.:

\[(600 + \text{per cent. water}) \times \text{per cent. Balling.}\]

100 - per cent. Balling.

Two mashes of 50 grammes of malt gave the following:

<table>
<thead>
<tr>
<th>I.</th>
<th>II.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specific gravity of the wort</td>
<td>1:0385</td>
</tr>
<tr>
<td>Average specific gravity</td>
<td>1:0384</td>
</tr>
<tr>
<td>Extract calculated by formula</td>
<td>63:85 per cent.</td>
</tr>
<tr>
<td>Moisture in the malt</td>
<td>7:60</td>
</tr>
</tbody>
</table>

5:192 grammes of wort was then placed in a flat-bottomed dish and dried at 105° C. to almost constant weight. Results, viz.:

<table>
<thead>
<tr>
<th>I.</th>
<th>II.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weight of extract</td>
<td>0:4520 grammes</td>
</tr>
<tr>
<td>Average weight</td>
<td>0:4521 grammes</td>
</tr>
<tr>
<td>Extract</td>
<td>54:25 per cent.</td>
</tr>
</tbody>
</table>

The same amount of wort dried at 70°-75° C. for about seventy hours gave:

<table>

<th>II.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weight of extract</td>
<td>0:4924</td>
</tr>
<tr>
<td>Average weight</td>
<td>0:4923 grammes</td>
</tr>
<tr>
<td>Extract</td>
<td>59:07 per cent.</td>
</tr>
</tbody>
</table>

(To be continued.)
The very numerous attendance at the gathering now being held at Budapest is not only an emphatic confirmation of the opinion entertained by Hungarians that their beautifully situated though remote capital is well adapted to be the seat of a congress of hygiene. In addition to the demonstration of that fact, which will afford general satisfaction, the large number of visitors from all parts of the world is also evidence that, unlike some other gatherings of a similar nature, the Congress of Hygiene and Demography cannot be characterized as a concentration of cranks. Among the subjects dealt with by the method of international congress, the care of public health and the study of the influences exercised by various local conditions of social life are of such prominent and inevitable interest from an international point of view that they offer a sound basis for the periodical repetition of each meeting. In this respect the present Congress at Budapest is to be looked upon as a significant expression of the importance attached to hygienic subjects, and the assembling in that city of more than two thousand visitors is an indication of the fact that it is rapidly advancing to the position of the metropolis of Eastern Europe.

To pharmacists this Congress presents an interesting aspect, inasmuch as it is the first occasion on which an independent section devoted to the consideration of pharmacy has been made a part of the official programme. It has not been by any strained interpretation of the functions of pharmacists, and of the objects of the art which they practise, that this result has been arrived at. It is rather a consequence of due appreciation of the demands which the present time makes upon pharmacy, and of the perception that preparation for satisfying those demands must be made by its followers. The inauguration of an era in which medicine is regarded not only as a means of curing disease, but also as having the still more desirable object of its prevention, has created for pharmacy and for those who are engaged in the practice of the art a vast new field for the useful exercise of their capacities as professional administrators of the increasing powers acquired by scientific investigation. From this point of view the Congress at Budapest marks an epoch in the history of pharmacy.

As the business of sections only commenced on Monday, we are unable to do more than record the fact, and defer further report of the proceedings to a future occasion. But it may be stated that in every respect there is promise of a very successful result. The official reception of visitors on Saturday by the municipal authorities of Budapest was of a most cordial and hospitable character, and on all sides proofs were given of the graceful and friendly politeness which is equally characteristic of Hungarians and Austrians. The frequent familiarity with other languages besides their own has also been a great advantage to many of the guests, and has tended largely to promote the formation of acquaintances, and to facilitate intercourse. The ceremony of opening the Congress, at which the Archduke Carl Ludwig, presided, was a particularly brilliant spectacle, though it was a source of no small regret that Great Britain was almost the only civilised country which was not officially represented. The reception of the members of Congress at court by the Archduke, in the evening, was an equally striking spectacle from the variety of picturesque costumes of the officials present. The number of delegates representing universities, scientific societies, municipal bodies, corporations, etc., is very large, and in most instances the delegates are present at the Congress, though it is to be regretted that in some instances they are conspicuous by their absence.

Time as a Factor in Education.

Probably no better enumeration of the qualifications of the ideal pharmacist has yet been published than that embodied in a descriptive account of the Illinois College of Pharmacy, recently sent out by the Northwestern University, Chicago. As his position is there defined, the pharmacist must be fitted to form a correct opinion with regard to the identity, quality, and purity of medicines, and to combine and dispense them accurately, applying for those purposes the best means which scientific training affords. To this end, he should be practised in qualitative and quantitative analytical methods and in the use of the microscope, and grounded in the scientific principles of pharmaceutical work, as well as in its practical operations. As a result, "he should be equally well prepared for the best professional service at the dispensing counter, to aid
the physician as the chemist of the medical profession, to act as public analyst, especially for the protection of health, to undertake the work of the manufacturing laboratory, or for any related technical pursuit."

In attempting to realize this ideal American pharmacists are influenced by very similar motives to the German "apothekers" who, as recently shown in the Journal (ante, p. 151), hold the view that the pharmacy of the future will be a hygienic institute adapted to modern requirements. In Germany, it is proposed on the part of the pharmacist that he should prepare himself for assisting medical men more fully than heretofore by putting himself on the same educational level as the latter, and similarly in America it is recognized that a longer special training will be required by the pharmacist of the future. It has therefore been decided by the authorities of three universities in the United States not to confer the title of "pharmaceutical chemist" until after the completion of a two years' special course, with about nine months' full work in each year, and the lead thus taken is being followed by several of the most prominent American colleges of pharmacy. There is little reason to doubt that the time is ripe for such a change, for it must be allowed generally that the realization of the ideal depicted will involve the attainment of a much higher standard by pharmacists generally, and this in turn will necessitate a longer period of preparation.

The importance of time as a factor in education is very clearly stated in an editorial article in the Apothecary for August, by Dr. Oscar Oldberg, Dean of the Illinois College of Pharmacy, who points out that success in pharmaceutical or other education consists not merely in the mastery of facts, their digestion and assimilation, but chiefly in such discipline of the mental faculties as will fit the student to use those faculties intelligently, successfully, and promptly. Such discipline of course requires a considerable amount of time, and cannot be obtained in the shop, as whilst working in the pharmacy there is little opportunity for the application of careful thought and deliberate study to the subjects included in the pharmaceutical curriculum, and shop training therefore cannot in any degree replace a proper college course of study. But, again, the discipline cannot be obtained by a very brief stay at a school of pharmacy, for the student cannot then be well trained, and if he leaves imperfectly prepared for his life-work, his subsequent opportunities and surroundings are frequently no longer favourable to as rapid development. Dr. Oldberg urges therefore that the minimum amount of time exclusively devoted to college training should be not less than forty weeks, and he concludes by asserting that there should be no question about the real necessity of an additional course of nearly twice that amount of actual school work.

EDUCATION DURING APPRENTICESHIP.

Whilst the question of the length of time that should be devoted to the educational course in pharmacy is an equally important one in this country, it is more difficult here apparently than in America to induce students to devote any extra time to college work. The system in vogue here has been briefly described as an unadulterated system of examination — the period of instruction wherever being insisted upon in connection with any of the British pharmaceutical examinations, and, except in a limited number of cases, no thorough satisfactory scientific and technical training being undergone by the numerous candidates presenting themselves. Though in practice necessity teaches them that some definite course of school instruction is requisite, and the great majority of candidates for registration as "chemists and druggists" have received a more or less limited tuition in the essentials of the examination syllabus, it is quite clear that they spend anything like sufficient time for the purpose. The time spent at a school of pharmacy is usually no longer than is absolutely necessary to acquire sufficient knowledge for examination purposes, and, brief as this period of continuous study is at best, its value is often yet further discounted by the fact that the students are at entry imperfectly or not at all prepared to commence the systematic study of the various scientific and technical subjects, a knowledge of which is required under modern conditions.

Now, the experience of the past fifty years has proved that British pharmacists have, by the aid of a regular study during apprenticeship, been enabled to dispense with a very prolonged course of college training, and yet hold their own amongst the pharmacists of the world, and there would appear to be no reason whatever why, with a reasonable amount of diligence, apprentices should not now, within a limited time after the expiration of their period of pupillage, be in great measure prepared to pass the qualifying examination. It would appear, therefore, that the present unsatisfactory state of affairs is in great measure undoubtedly the result of mispent time or misplaced labour during the period of apprenticeship, when the elements of the various sciences upon which pharmacy is based may, under existing conditions, best be acquired. At the same time it would be inadvisable for candidates to rest content with the knowledge they may have acquired during pupillage, and depend upon it alone, though such knowledge, if systematically acquired will always be of value and effect a considerable saving of time later in the student's career. The chief desideratum is that these early studies should be conducted systematically, so that progress will be sure, though gradual.

Accordingly, to the end that pharmaceutical students should have some better guide in their elementary studies than now seems to be generally available, it has been decided to publish in the Journal for September 15 a number of articles specially addressed to them. These will deal with the different subjects in the pharmaceutical curriculum, and the object kept in view throughout will be not to suggest methods of preparing for examination, but to indicate to some extent how students may enter upon a proper course of education, to which examinations will necessarily be subordinated.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The next reunion of members of the Chemists' Assistants' Association will be on September 15, when an excursion will be made to Walsford.
The next communication was the following:—

NOTE ON PHOSPHORUS PILLS.

BY R. H. FARKER, F.C.S.

Phosphorus pill-mass prepared with a fatty or resinous basis, beside being troublesome to prepare, difficult to preserve, and in some cases impossible to digest, is often found inconvenient at the dispensing counter on account of its bulky character and its disposition to produce crumbly masses when combined with other ingredients. Pills freshly prepared with a solution of phosphorus in carbon bisulphide diffused through liquorice powder are not open to these objections; it seemed, however, desirable to determine whether such pills are permanent, and contain the full amount of unoxidised phosphorus.

I will first describe in detail the exact method adopted in preparing, for example, two dozen pills.

Take of phosphorus, the prescribed quantity for 24 pills.

Carbon bisulphide .......................... 30 minims.

Liquorice root, in powder ................. 24 grains.

Glycerin .................................... 4 minims.

Tragacanth gum, in powder .............. 2 grains.

Syrup, a sufficient quantity.

Disperse the phosphorus in the bisulphide, pour the solution upon the liquorice powder in a pill-mortar, stir uniformly within the smallest possible space, by means of a spatula, until the solvent is nearly evaporated (no portion should be allowed to assume an appearance of dryness); as soon as the mixture becomes nearly solid, and while still moist with bisulphide, add a sufficient quantity of syrup to form a soft pill-mass, and incorporate quickly until homogeneous. Any other prescribed ingredients may now be added aequam stans, and the mass divided into twenty-four pills without undue exposure; no coating is necessary.

Not finding a recorded method for the determination of free phosphorus in pills, I decided to try extraction with carbon bisulphide, oxidation to phosphoric acid, and final titration with standardised uranium solution. This method gave very fair results. A solution of uranium acetate was prepared and titrated against acid phosphoric; its value was found to be 1 c.c. = 0.00238 phosphorus.

Experiment 1.—0.2 gramme phosphorus was oxidised with nitric acid in presence of a fragment of iodine, evaporated until nitrous fumes ceased to be evolved, diluted with water, slight excess of sodium bicarbonate added, then assayed with acetic acid and made up to 250 c.c. with water; of this solution 40 c.c. = 15.1 c.c. uranium solution, i.e., 0.188 phosphorus found.

Experiment 2.—0.0472 gramme phosphorus was dissolved in carbon bisulphide, evaporated to dryness, the residue oxidised, and an acetic solution prepared as in experiment 1, diluted with water to 50 c.c. of this solution 20 c.c. = 8.1 uranium solution; i.e., 0.0465 phosphorus found.

Experiment 3.—0.4 gramme phosphorus in 2 c.c. carbon bisulphide poured on 6 grammes of liquorice root powder and made into 100 pills, in the manner described in the early part of this note. Ten of these pills were kneaded in a glass mortar with several successive quantities of carbon bisulphide, the mixed solutions evaporated to dryness, the residue oxidised, an acetic solution prepared as before and made up to 50 c.c. with water. Of this solution 20 c.c. = 6.7 c.c. uranium solution; i.e., 0.0385 phosphorus found. The remainder of these pills, examined in a similar manner at intervals of three months showed practically no diminution of phosphorus. A sample of pills is on the table prepared in the same manner, each containing 50 of a grain of phosphorus, and without any kind of coating; they have been kept in an ordinary pill box, occasionally opened and the pills handled since January, 1889—a period of nearly six years. They evidently contain the phosphorus exactly as when first made, for the slightest superficial solution produces phosphorescence, and a central section exhibits the same phenomenon over the entire surface. These pills rapidly disintegrate even in cold water, and without the assistance of massage.

The conclusions are obvious—that phosphorus pills may be easily prepared by this method without material loss or oxidation, that they are permanent, and that no coating is necessary for their preservation.

Mr. Ing said he was quite sure they might congest the author on his mode of making phosphorus pills; there were very many formulae at present for this particular preparation, and as far as he was concerned, he thought nothing ought to be attempted with phosphorus or similar substances unless you could effect entire solution. It ought not to be allowed to enter into combination, except in a state of solution. He entirely agreed with what had been said about the comminution rather than solution of phosphorus by oil or fat; they got it finally comminuted, but no more, and he thought that was more or less dangerous. Officially they were bound to follow the instructions of the B.P., and, following it with great care and attention to temperature, they got a fairly good result; but he objected to that formula altogether, because the phosphorus was not combined in a perfect state of solution.

Mr. Martindale said after all was it not a form of comminution in the method followed by the author, who got the phosphorus in solution in bisulphide, and then precipitated in the pill. He had paid a great deal of attention to this subject for the last twenty-five years, and he must say he preferred to keep the phosphorus in solution always. The formula which he published some twenty years ago was that of dissolving it in cacao butter, and then precipitating it in that substance which could be easily rolled out into pills, and if they were fairly freshly prepared, the phosphorus was in the most active condition in which it could be administered, and in that condition was easily digested. The phosphorus Mr. Farker mentioned was only in a precipitated condition. It melted at 110°, above the temperature of the body, and in that way could hardly become completely digested when swallowed, and, therefore, he hardly thought the full dose of phosphorus would act. It was true they often had to combine phosphorus with other ingredients and other processes of dissolving it in bisulphide and adding the other substances might be convenient. Mr. Groves suggested about a year ago a mode of emulsifying phosphorus to the finest condition by following Mr. Parker's process to this extent—dissolving in bisulphide, adding that to yolk of egg, stirring quickly, and, after adding the emulsifier, to prevent oxidation. The emulsification of the bisulphide solution with yolk of egg was quick and complete, and on afterwards adding some liquorice powder you produced a mass which Mr. Groves suggested an ingenious way of keeping. He smeared the stopper round with honey and put a little cotton wool inside with a few drops of oil, the mode of preserving phosphorus pill mass might be used for any mass containing phosphorus, but phosphorus pills would not keep for any length of time.
He had some made on the 14th of April last year, and they were now completely oxidised: there was no glow of phosphorus about them, although they were varnished. He held that phosphorous pills should be freshly made. As to nostrum-mongers making these pills, he said it was an absurdity. Phosphorus should be dispensed as quickly as possible, and not kept in stock.

Mr. Gerrard said that at the time when phosphorus was first introduced he remembered very well the trouble he had to get preparations of it in a suitable condition. The most common resin as a solvent, but that was improved upon by Mr. Abrahams, of Liverpool, who suggested balsam of tolu. That suggestion was taken up by the pharmaceutical authorities, and the method introduced as the basis of the official pill. Since that time there had been considerable improvement made, and Mr. Martindale himself had done excellent work in that direction. If Mr. Parker had looked up the 'Year-Book of Pharmacy' he would have found that in 1878 it gave a process which was quite on parallel lines with the one now brought forward. He suggested then that they should be made by dissolving the phosphorus in a suitable medium, pouring the mixture in a bottle, and powder tragacanth powder, moistening it, adding a little chloroform to prevent oxidation, and rolling the mass out quickly.

Mr. Hardwick said the point of this paper was not the way of making phosphorus pills, but a statement that they would keep for a long time without oxidation. Mr. Parker thoroughly condemned all kinds of fatty bases for phosphorus pills. Now they often had to dispense phosphorus pills with a number of other ingredients, such as nux vomica, cannabis indica, quinine, or even strychnine and opium. He thought it was a very useful manner of obviating the difficulty of weighing out minute quantities of phosphorus, such as half a grain, or less, was one of the suggestions of which he got from an early edition of Mr. Martindale's book. He dissolved the phosphorus in bishulphide, and added a fatty base, the most convenient being suet, with a small addition of vaselin and kaolin to make it sink in water. Then he kept the composition under water, as he kept stick phosphorus, and taking out small portions and blotting off the moisture he was able to weigh it without difficulty, and make up pills easily which rolled well and kept their shape.

Mr. Williams said he was particularly interested in Mr. Parker's paper, because it was contrary to all recent opinion as to the stability of phosphorus in pills. They were always taught that it certainly did oxidise, and he was astounded to hear that a preparation had been kept six years and still exhibited phosphorescence. A short time ago he had seen that amorphous phosphorus had been highly recommended as producing exactly the same result as ordinary phosphorus, but he had not been able to confirm the statement by anyone who had had experience of its use, but it seemed to him the advantages were considerable, provided its medicinal value was equal to that of ordinary phosphorus.

Mr. Gunney said he remembered some years ago dispensing a prescription containing 2 gms. of amorphous phosphorus in each pill. He at first thought the dose must be excessive, and consulted the medical man he said it was all right, 2 gms. of amorphous phosphorus was a perfectly safe dose, and would have no more effect than one-thirtieth or one-fourth of a grain of the ordinary crystalline form. The prescription was dispensed several times during a week or two, and he never heard anything more about it.

The President said he did not wish to stop discussion, but everyone would agree with his own experience that his natural life was not long enough to indulge in perpetually going back to the rudiments. Allen and Hanburys in the Pharmac. Journ. for May, 1876, published a formula for phosphorus pills by solution in bisulphide of carbon, and mixing with soap, got good results. Phosphorus pills should be prepared as required. Essentially this form was the same as Mr. Gerrard's, except that there was soap and gum in it. It had been reproduced in the 'Art of Dispensing,' and was one by which twelve, twenty, or a million pills could be made, and it had been used by many pharmacists as a basis for preparing a thing of this sort and save themselves the trouble of needlessly experimenting over and over again. That pills should keep for ever was not expected, or that pills made on the other side of the Atlantic should be taken on this side was ridiculous. At the same time, they did not want to make every preparation day by day. He had made pills according to this formula combined with other ingredients, and they were practically unalterable for a long period. It so happened that this formula in combination with other ingredients -was on the shelves constantly, and when he saw this note he was to be read he told his assistant, and he had a box of poles he could find, to examine them, and to see whether they were soluble and contained unaltered phosphorus or not. He gave him a report to the effect that they were as soluble as pills could be, dissolved at the temperature of the stomach in a few minutes, and contained practically unaltered phosphorus. When they had a formula which was practically so satisfactory as this, it was not desirable to spend their time in endlessly studying rudiments when there were great chemical problems in front of them and more important things to be studied.

Mr. Parkinson said that Mr. Martindale's formula of phosphorus dissolved in theobroma was no doubt very satisfactory if you could roll out the pill mass as combined with other ingredients. But he found the formula now suggested gave a mass that could be mixed with almost every ingredient that came to the dispensing counter. Phosphorus should be administered in solution probably, but in this case he took 24 gms. of liquorice powder, dissolved the phosphorus in 30 minims of fluid, and made a sort of mud of it, and by that means every cell of the liquorice powder was equally permeated by phosphorus. The pill when finished dissolved readily in water, and if ingested disintegrated directly into an enormous number of minute particles of phosphorus. Whether that was different in physiological action to phosphorus dissolved in theobroma he could not say. He must disclaim any idea of novelty in the formula. He did not claim that in the paper Mr. Lloyd Williams had referred to the value of amorphous phosphorus. He had repeatedly dispersed large quantities of it, and it was stated by many authorities that it was inert. Certainly very large doses of it had been given, and if quite free from any other form of phosphorus it probably was inert. Particular attention must be given to see that it contained nothing but amorphous phosphorus. The President complained of his returning to rudiments, but he would not have taken the trouble to investigate whether these pills, after being kept for six years, were still unchanged; if he had found any record of that he could not find any statement as to the keeping properties of pills made in this way, or whether, after a week, they would contain free phosphorus or not. He simply conducted this work for his own satisfaction, and recorded the results to save other people from going through the rudiments.
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS.

The following paper was next read:—

THE NOMENCLATURE OF OFFICIAL REMEDIES.

BY JOSEPH INCE.

In view of the advent of an imperial pharmacopoeia, I venture to say a few words upon this subject. There is always a fear when the word nomenclature is mentioned lest some fanciful theory should be introduced, ingenious, possibly, but of little practical use.

I have no speculative suggestions to advance, and all I ask is that as new official remedies claim adoption, which I think that Latinism should be given, the construction of this nomenclature should follow the ordinary rules of declension which are commonly known and accepted. We have already in the body of the pharmacopoeia several words which have been left as indeclinable, while the Addendum is in evidence that their number is on the increase—a matter which reflects on the scholarship of the day, and embarrasses the prescriber, who, owing to the technical arrangement of a prescription, has to frame a terminology with declensions of his own.

I would leave untouched the whole series of undeclinable nouns, thus;

1. Neuter nouns ending in -a. (Third declension).
   Example. Animal, animâlia.

2. Neuter nouns ending in -e. (Third declension).
   Example. Alcohol, alcoeholâ.

3. Masculine nouns ending in -a. (Third declension).
   Example. Sapo, sapone.

Other nouns at present taken as indeclinable, as amy’l and sambu’l, are open to discussion, and with respect to such, differences of opinion would exist.

I should like to see the title syrupus chloral-benzoin from the Pharmacopoeia, as it has long been from the prescription of the practitioner, and let it enter into uniformity as syrupus chloralis. Sulphonâl (in the Addendum) enters as yet into no other preparation, but should that happen, its inflexion would be already determined. Meanwhile, the prescriber writes sulphonâlis grâns quâdecim when he would indicate the dose.

If we say, as we certainly do, guided by the Pharmacology—

A. Camphore (Alcoholis solutæ) 3i.
   or

B. Camphore (alcoholis ope in pulv. sedi, sedi, græcâ) 3i.,

surely the title emplastrum mentholi should not longer be retained, but give place to emplastrum mentholis, and thymol, with all companion words, would follow suit.

Former editors have foreseen the difficulty which occurs in matico and pimento, and have intitulized both as infusum matricis and aqua pimentæ. Let them stand, especially the latter, which comes from pimenta; but it seems advisable, in anticipation of the future, that other or new terms which may resemble sapo should have the same declension, while kine and cussio might obey the same rule. If we say linimentum saponis and cataplasmâ carbonis, why say tinctura kini and infusum cussii?

In conclusion, let me express the hope that the above remarks may not be considered in the light of a mere literary excursus.

The class of words to which attention has been directed must grow and multiply, and the full inconvenience of a heap of undeclinable pharmacopoeial titles will be felt.

I advocate no novelty in nomenclature, but only recommend the systematic adoption of known grammar rules to meet new requirements.

The President said in view of the possibility of a new pharmacopoeia being proceeded with at an early date this was a subject which would probably provoke some amount of discussion.

Mr. Martindale asked what objection Mr. Ince had to indeclinable words such as thymol, menthol, and sulphonâl. The custom had been that when a noun was taken from one language into another, as when Greek terms and Arabic terms were introduced into Latin, they were introduced indeclinably, and he thought that should be the rule, and with such words as thymol, sulphonâl, chloral, amy’l, and others it was best to make them indeclinable. What object was there in making them declinable? They could understand from the context of the prescription what the meaning was. When they saw amy’l nitrâs they knew it was in the genitive, and the same with chloral hydrâs. When they saw thymol, sulphonâl, chloral, amy’l, and others it was best to make them indeclinable. What object was there in making them declinable? They could understand from the context of the prescription what the meaning was. When they saw amy’l nitrâs they knew it was in the genitive, and the same with chloral hydrâs. When they saw thymol, sulphonâl, chloral, amy’l, and others it was best to make them indeclinable. What object was there in making them declinable? They could understand from the context of the prescription what the meaning was. When they saw amy’l nitrâs they knew it was in the genitive, and the same with chloral hydrâs. When they saw thymol, sulphonâl, chloral, amy’l, and others it was best to make them indeclinable. What object was there in making them declinable? They could understand from the context of the prescription what the meaning was.
what had been accepted as the scientific termination of those two words. Glycerine was spelt in Watts's 'Dictionary' without the final "e," and it was so consistently in scientific work, but the common compound was to give the final "e." If the "e" were dropped it would look as if it were some thing else.

Mr. Atkins said, as assembled as they were in a great classic institution where, of all places, Greek and Latin would be most strictly and authoritatively defined, he could not hold it as a practice, or an assent, to omit the thought, which was in harmony with Mr. Ince's opinions, that there ought not to be anything such as was called in his early days "dog Latin" in pharmacy. Their Latin ought to be up to date, and the Latin of the Pharmacopoeia and that of the apprentices should be as far as possible strictly in harmony with their classical instincts.

The President said he could only assume, seeing so few joined in the discussion, that they would all sit at the feet of Mr. Ince on a classical subject. He hoped the future pharmacopoeia authorities would do so, and listen to what he had to say. He could quote an instance that when a term was coined there was exceedingly inconvenient that those terms should be submitted to classical authorities and subjected to classical rules, because if they looked at the advertising pages of the press it would be seen that they often went to Southampton Buildings and registered a term and obtained a proprietary right in it, and it would be exceedingly inconvenient if those words had to submit to classical laws. Anyone who had any regard for scientific nomenclature must deplore the way in which words came into use. What was meant by such words as "dermatol?" In their early days they examined students in Latin; they did not do so to teach them dog Latin, but that they should be able to correctly translate a prescription written in Latin. He hoped that this short paper would have considerable effect, and that the pharmacopoeia authorities would not only make the new edition worthy of England and of the nineteenth century in the formulæ selected, but also in the names, and in the manner in which they were used. He would not criticise the United States Pharmacopoeia in this respect, because America was a law to itself; it observed all that was convenient, and nothing more; but with regard to setting the fashion for the use of the English or Latin languages they need not go across the Atlantic.

Mr. Ince, in answer to Mr. Martindale, said he could not see the advantage of wading about utterly adrift, without rule and guide in the great number of new preparations which must of necessity be introduced. In order to keep these within the bounds of common sense, and not what was called classicality, he had taken special pains to cut down the paper to one-third of what it might have been, and to confine his remarks to suggestions which he thought were of use and might be adopted. That would be advocating introducing some plain, definite rule, known to everybody who had passed the fourth form, by which a word with a certain termination, and that belonged to an ordinary thing and not to a novelty, should follow the ordinary rule for its declension. If you had a word introduced into the pharmacopoeia that termination, why on earth should it be left indeclinable. Those who came afterwards would think it was owing not to any theory, but rather to a want of acquaintance with the subject. He had very carefully limited his suggestion to the three plain ordinary declensions. When you had words with the same terminations, why should they all run adrift. Those who prescribed had by necessity to employ a certain definite mode of conveying their ideas, which was called a prescription; they could not help themselves. They had to put all their quantities in figures, which had to be translated properly by candidates for examination. They had to know the correct form of each of these cases. The ingredient which formed the prescription itself had from necessity to be put in a certain case, the genitive. The result was the medical profession was far in advance of what the rule of construction laid down. They took these words in "at" and made them "all," and of course no answer. He wanted to get out of any notion of his own, or any arbitrary formation. All he asked for was that ordinary grammatical rules might be followed. Mr. Martindale asked what was really the object, because they could guess by the context what was meant. But they did not allow the students to pass in that way. They took care when they had a prescription before them that they should be able to translate it correctly, and not only to understand the meaning, and why they should require from students that they did not require from the official pharmacopoia he could not understand.

The last paper read was on:

**ENGLISH MEDICINAL RHUBARB AND HENbane.**

**By Richard Usher.**

Rhubarb—Although the introduction of medicinal rhubarb into England is dated by Parkinson as far back as 1639, no real experiments in its culture and preparation for medical use appear to have been made till 1782, when a quantity of seed was sent from Russia by Dr. Mounsey, from which period till about 1800 it was successfully grown in small quantities by many scientific men, after which it was cultivated at Banbury on an increasing scale, and is now known in the commercial world as a general article of trade, and not only is it consumed in considerable quantities in this country, but is exported largely to various parts of the civilised world. The origin of the plantations of rhubarb in my possession, and now extending over forty acres, will be best traced by the following extracts from the 'Transactions of the Society of Arts.' In 1789:—"The Society, in consideration of his merit, and to promote as much as in them lies the growth and cultivation of so valuable a drug, voted their silver medal to Mr. Hayward as a bounty." In 1794:—"In the following year respecting the growth and cure of rhubarb have been received, the gold medal being the premium offered for cultivating the greatest number of plants, was adjudged to Mr. William Hayward, of Banbury. The following is the testimony of Dr. Pereira: In 1789 Dr. Hayward obtained a silver medal, and in 1794 a gold medal from the 'Society of Arts' for the cultivation of English rhubarb. Dr. Hayward died in 1811, and the plants were purchased by his grandfather, Mr. P. Usher.

As a proof that even at this early period of cultivation English rhubarb was considered by the confidence of scientific men, it may be stated that in 1794 rhubarb of British growth was used at St. Bartholomew's, St. Thomas's and Guy's Hospitals, and being experimented on at several others. According to the testimony of Sir Alexander Dick and Dr. Bartrum, Edinburgh, in 1784, but little rhubarb was used by the apothecaries of that city, except that which we produced in Scotland, and it was considered in a respect inferior to Russian. About the same time English rhubarb was put to a severe test at Bath by Drs. Falconer, Parry, and Fothergill, all of whom attested its merits. Dr. Falconer remarked that the specimens submitted to them were of the external marks to the character of the foreign; the they were rather inferior in delicacy of taste to
Turkey, but superior in other respects to the East India. In 1810 Dr. Thornton, then lecturer on botany at Guy's Hospital, referring to the encouragement given to the cultivators by the Society of Arts, made the statement that the plant had been affected in the same way as tobacco. He showed both the ardour of this respectable Society in encouraging the growth of this useful article and the persevering industry of some gentlemen in overcoming all the difficulties attendant on introducing a new plant into cultivation, and their patience as well as their application in persevering with the prejudices of such as cannot persuade themselves that a drug of British growth can bear competition with what is sent from foreign countries."

If at a later date the prejudices against English rhubarb increased, there must have been other causes than those existing on the first introduction of the plant. One cause of the subsequent change in public opinion may have arisen from the partial introduction of new varieties of the plant. From the earliest period in its history there appears to have been a confusion in the evidence as to its real character, and whether foreign rhubarb was produced from the Rheum officinale or R. granatum. This was a question of great importance for many years an unsettled question. At the present day, however, in addition to these varieties we have a further supply afforded by Rheum officinale, derived from the plant introduced into this country in 1667 by the Late Daniel Hanbury as a source of the true Asiatic rhubarb. As far as the question relating to rhubarb grown in Great Britain, the stronger probability is, that after it was imported, several varieties were produced by repeatedly propagating from seed, when a discrepancy was observed at variance with the earliest descriptions recorded. To show the extent of those changes, I may remark that in the last instance in which I have examined the effect of successive cultivation about forty years since, I found the stalks and leaves more than double the size of those produced from offsets; a circumstance sufficient to account for the introduction of such varieties as the Victoria and other large sorts now so common in our gardens, which when propagated from seed still keep working change upon change. So convinced have I been for a long time of the injurious tendency of this system, that I have studiously avoided the use of seed altogether, and the plant has so far recoiled to its original type that I consider it the best I have grown in thirty years. It is a fixed trait in the cultivation of medicinal rhubarb, as it is in most bulbous plants, that if produced from offsets only it ceases to produce seed, and it raised from seed, each succeeding generation produces seed also, adding variety to variety almost indefinitely; assuming, as an incontrovertible fact, that the plant has now for about a lengthened period been propagated from offsets as to be incapable of bearing seed, it will guarantee the conclusion that if during a number of years when its cultivation was pursued by a larger number of growers for the purpose of making experiments, and each one in his way to enlarge its growth reverted to seed propagation, it degenerated from external causes, it is equally logical to infer that, the causes having ceased which led to its deterioration, it has now regained its specific distinctiveness, and is not likely to recur any longer into any transition from its central type. It is the conclusion of the author that the previous deterioration of the plant for medical uses which caused the strong prejudice existing for many years against it, and the remaining doubt still expressed respecting the real properties of English rhubarb, but that a powerful reaction has taken place in its favour since the plant has been restored to its primitive form of development there is most ample testimony, not only in the increased demand for it at home and abroad, but in the evidence of eminent medical practitioners. In addition to the improvement which became apparent in the plant by the entire exclusion of seedlings, an important change took place in the mode of drying by exchanging a high artificial temperature for a more gradual one, the process in the first stages being effected by the application of a strong current of atmospheric air, which has not only greatly condensed the root and rendered it less porous, but has given it an appearance far more attractive to the eye. The progressive but certain destruction of all former prejudices existing against the use of English rhubarb may be added from facts much stronger than theory. The first is that in 1845 the extent of land appropriated to the cultivation of the plant did not reach ten acres; whereas now it has reached upwards of forty acres, and even this is quite insufficient to supply the foreign demand for trimmed English rhubarb. If the home consumption of this drug had remained stationary the export trade alone would have afforded every facility for extending the plantation, a fact most strikingly shown by the article being sent to ports of foreign cities, from which East India rhubarb is sent to Great Britain. A large proportion of the trimmed rhubarb has for several years been shipped to the American market, where it has become a regular article of commerce.

Henbane.—Through some erroneous impression which has long existed, and still continues, respecting this very important plant, the first year's growth is spoken of as the annual, than which nothing can be more palpably wrong, as the two articles when produced for use vary as essentially in their external appearance as in their constituent properties, applying this simple test only, that the annual plant when dried contains both of leaves and awnssems, whereas the first year's growth of the biennial must necessarily consist of leaves only. Assuming that when the second year's growth of the biennial plant cannot be procured recourse must be had to the first year's growth as a substitute, the pharmacopoeia should have made known the comparative strength of the latter. No objection could have been made to such directions when it could be shown that a second class article must of necessity supplant a superior one, as occurs doubtless not only in this but in many other medicinal preparations. If in the use of the two separate articles nolice was taken of the fact that the same instructions are carried out, namely, to use two ounces and a half of the dried plant to a pint of tincture, and one should prove to possess two or three times the strength of the other, it assumes a serious aspect in the administration of so important a medicine. We require a new definition altogether of the plant when dried for use. Instead of making the two divisions only as at present, annual and biennial, it should be classified as follows:—

Biennial henbane of second year's growth;
Biennial henbane of first year's growth;
British annual henbane;
German henbane.

This would at once simplify the question, and prevent those erroneous views which have so widely prevailed amongst all parties concerned in its preparation and use. It will be seen that I have reversed the above classes in the order of their value. The two last-mentioned, the British annual and the German, although most extensively used, are so thoroughly undeserving notice, that they require mention only to guard the public against their use altogether. Of those two the British annual is perhaps preferable to the foreign, and its appearance, unfortunately, approximates sufficiently close to the second year's growth of the
biennial plant to enable the vendor to pass it as such; and if no other criterion existed than that it possessed the apparent virtue of being efficient to detect the imposture. Independently of this test, the leaves will be found much shorter, and occasionally will be seen a pure primrose colour blossom, which never occurs in the beautifully streaked blossom of the biennial; but the very fact of so remote a resemblance in the sample as this, that blossom being generally so much like the blossom of the biennial, leads to the very erroneous conclusion that it is the same plant.

Owing to the extreme price which the dried biennial plant of the second year’s growth has realised in former years, the consumers have not given that encouragement to its production which its intrinsic value merits. The great difficulty, however, which has thus been felt till very recently, that of not being able to obtain a supply except at a most exorbitant price, is now to a great extent obviated. After a long and careful study of the cultivation of the second year’s growth, success has been achieved in preserving the plant from the attacks of insects to which it is ordinarily subject, and by this the loss and temptation to substitute inferior varieties, to which both growers and consumers have been exposed, is prevented.

The President said he ventured to think that this paper, although written by a grower of herbs in the county, was of particular value, and he thought whenever the Conference went anywhere where there was some natural product or herb cultivated which was used in medicine, it would be very useful to have a paper on the subject. He certainly thought Mr. Usher had contributed something of value, both from a historical point of view and also from the practical facts he had recorded as to the cultivation of rhubarb from offsets instead of seeds. If the demand for this English rhubarb only grew, it would be a profitable field for English farmers. Henbane also was a drug of extreme importance, and he had not the least doubt everyone present would support him in saying that the uncertain estimation of the value of henbane was doubtless due to the fact that several batches of crude and manufact train tinctures and extracts. The Pharmacopoeia clearly defined what henbane should be, but there was strong probability indeed that other varieties did go into medicinal use, and that was one of the causes of the difference of opinion which existed as to the choice as a diuretic and therapeutic value of henbane and its preparations.

Mr. Drucoc said there was a great deal to be said on the point of general hybridisation. Mr. Usher seemed to have cultivated sometimes one variety of rhubarb and sometimes another, but they were closely allied species, and hybridisation went on. Those products were so varying that you never knew what you had got. He might accentuate that by an illustration. Their late lamented townsmen, Dr. Romanes, was making experiments on the hybridisation of animals, and he found that the progeny of the white albino rat and the common brown rat were not plebeial as was expected, but simply brown. In the case of the second generation of brown rats, the offspring of the white and brown, were plebeial. So with hybridised plants, the second generation might come true, but the third might be as variable as possible. Mr. Nodont, experimenting with stramonium, found he could stamp out the clump of one particular variety and after eight generations of cross fertilisation, but he had not at that time got the stable parents you would have at the first, but instead of that a plant which varied almost infinitely, not in the direction of one of the assumed parents, but in an unexpectedly different way. That might account to some extent for the extreme variability of the rhubarb field.

Mr. Reynolds said he had rather a special interest in this subject, inasmuch as the rhubarb fields at Banbury were connected with his earliest recollections. Those who indulged in horticulture unquestionably rejoiced in this variability of nature, and the variety which the rhubarb, from other cultivations, seeds of plants which were supposed to be nearly the same, but the horticulturist, like Mr. Usher, knew how to produce uniformity by taking cuttings instead of sowing seeds, and, therefore, it was in their own hands very largely. There were not many medicinal substances which were made the subject of cultivation instead of collection, so large if any of what came to them had been collected from Nature’s wild garde, but they were nearly all old enough to recollect what cinchona had a wild origin, when forests were cut down in South America, and how rapidly science provided cultivated cinchona, and what enormous benefits were received from Mr. Moos, in London, a memorandum showing the price of quinine in the year 1850, per ounce. If they wanted rhubarb cheaper, Mr. Usher could supply it, but whatever had been rewarded twice by the Society of Arts, a national benefit was certainly worthy of being introduced here.

Mr. Ransom thought they were indebted to Mr. Usher for his interesting communication. The rhubarb was almost the only example of an English-grown drug that was not supposed to be of equal value to the foreign. Notwithstanding the extent of the cultivation of rhubarb, it was considered improbable, it would be interesting to have it proved and it should be proved. Certainly there would be scope for much larger cultivation if it could be shown that medicinally it was as useful as the Asiatic. With regard to henbane, he could also emphasise what Mr. Usher said with regard to the confusion between the annual and the biennial. The two drugs were entirely different. When the annual was ordered, the leaves of the biennial plant were often intended. As the order of the value in which they were held, he was not quite sure whether Mr. Usher meant the value be price or the actual medicinal value of the different kinds. Early impressions were very difficult to get rid of. On the one hand, henbane was a very beautiful plant, as well as interesting, and produced rosette leaves the first year, then it grew up into a handsome plant, sometimes as tall as ten feet. Naturally, being taught that the branch henbane was the best, when they saw the plant it was best, naturally, but when he began to grow it, and it ceased to grow, the one being a comparatively insignificant small plant, you were led to consider that the one which you had been taught was the best and had seen was the most handsome plant, naturally must be the best. It often happened when you came to put matters to test this in practice, that the large banks, and the small banks were the better in quality. It was much the same with henbane. If you took the same henbane leaves, not stalks with the flower tips,
submitted them to analysis to extract the alkaloids, they would be found to yield as near as possible the same percentage of alkaloids as the first year's biennial leaf or the second year's biennial wood and you would get the henbane which would yield a much more active preparation than either, you must take the biennial root of the first year's growth when it was very large. You would get from that three or four times as much alkaloidal matter as from the leaves or tips of the plant. A general deal might be said about the quality of henbane in connection with the mode of treatment. If the crop, whether annual or biennial, were carefully collected, rapidly dried with a bright green, well preserved, not tied up in paper parcels or thrown in corners, it would keep for a considerable time, and in the course of three or four years would be found almost as good as when first prepared. He had shown by analytical figures that a badly dried specimen, old and brown, had undergone a certain amount of change, and the alkaloidal properties had become low; it was, therefore, necessary that farmers should take care in preserving it wherever the place of cultivation, the soil, and the climate were not suitable for a biennial crop. If you took a little henbane—the pure base, not the salt—and warmed it in water, it would lose 20 per cent. of its alkalinity by conversion into an acid body with a new base. He was pleased to hear from Mr. Usher that he had been able to get rid of those pests which were such a nuisance in connection with henbane cultivation. It would have been interesting had he told them how. He had cultivated it on a small scale, and found the insects very troublesome; they would consume the whole crop in a few days. The biennial henbane was generally looked upon in the market as the best article, and was high in price, but he thought that was purely sentimental on account of the flowering-tops. The first year’s growth of the biennial henbane was undoubtedly as good in alkaloidal quality as the second year’s biennial tips, and the first year’s or annual henbane, if the crops were well farmed, was practically as good as the other.

Mr. Usher said he was not an analyst, and was not able to add anything on that part of the subject. The substance he used to protect henbane against insect pests. The attacks of insects was a mixture of salt, soot, sulphur, and lime, in equal quantities.

The President, in seconding the motion, said he was sorry to say that the remaining papers would have to be taken as read, but they would be published in the Quarterly Journal. The paper would be received with pleasure. Any letters or communications on the subject treated of, which would practically have the same effect, he would only add that the meeting was unanimous.

Mr. Lloyd Williams then moved that the members of the Committee, who had conducted their work in a very able manner during the past year, be thanked. He thought that in the interests of pharmacy the work had been perfectly safe, and they had to thank them very heartily for what they had done.

Mr. Linford, seconding the nomination, said the action of the Committee had been of such really practical use to chemists and druggists that next year, perhaps, to the Pharmaceutical Society they owed as much to the Formulary Committee as to anybody else.

The resolution was carried unanimously.

Mr. Muntz, on behalf of himself and his colleagues, thanked the meeting for the honour of re-election. He said there was still work to do, and a new edition of the formulary would be ready in a week or so.

Place of Meeting for 1895.

Mr. Bridge, of Bournemouth, said it was with very great pleasure, but with a great amount of trepidation, that he came forward to offer a unanimous invitation to the Conference to visit Bournemouth in 1895. They could not compare it with the Conference's visit to Plymouth, but they would treat the Conference as a foreign visitor to the county, and would do everything in their power to make it a memorable Conference. Mr. Bridge also said that there was no other Conference in the world which was so thoroughly under the control of a local Conference than the one which was going there. The Conference was not a voice raised against it, and
whatever Oxford or any other town had given the Conference, if they would accept their invitation for 1885 he could safely say that no city or town would ever have exceeded the welcome they would give them.

Mr. Toone said he should like to add just one word in support of the invitation Mr. Bridge, who was president of the local society, had given. He had said very truly that they had nothing to show like those grand historic buildings which they had looked at for so much pleasure during the five or six days. Bournemouth was a new town, though as far as population went it was as large as Oxford, and there were some rude people who, speaking of their growth, compared it with one of the edible fungi, but for all that, although they might have grown rapidly in the past, they had a large, important, and beautiful town at the present moment, and they believed they had a very great future before them. There was one pharmacy in the town which had over its door the legend "Established in 1844," and they always passed that gentile as a mark of the town's growth, and looked on him as one of the links with the past which the Conference that they would do their utmost to make the visit a pleasant one. Nature had endowed them with beautiful gardens, with forest trees, and that which was such a charm in the summer time for those who lived in big cities, a beautiful sea.

Mr. Germain proposed that the kind and hearty invitation to the Conference by the representatives of Bournemouth be accepted. Mr. Bridge had said there was no other Oxford, and he might say there was no other Bournemouth. He had seen and learnt something of the rise of Bournemouth, and there was no doubt that it was a beautiful child which they would all like to go and see. Even those who had been before would like to go again, and he might say that they would have something of the old as well as the new. There was Christchurch Abbey, and Wimborne was not far off. He had spent many happy days in the district of the beautiful New Forest, which was very near with its botanical riches, and he hoped that the ladies now present and many others would also meet them at Bournemouth.

Mr. Ward (Leeds) seconded the proposal. They had had some reference made to the contrast between the antiquity of Oxford and the youthful vigour of Bournemouth, and it might be agreed that this contrast was a strong argument in support of the motion. The President said their friends from Bournemouth would pardon him for saying one word about this new departure before putting the motion to the meeting and heartily supporting it. This year they had not an invitation from the town where the British Association was to meet, but a great deal of misapprehension had gone abroad with regard to the Pharmaceutical Conference, and he hoped that they would hear with satisfaction that he had said aside some newspaper paragraphs, the result of gossip which was quite wrong, and he was quite sure would deter small communities from the pleasure which they would have in receiving the Conference. The Conference did not require, as the Motion did, a guarantee fund; it did not require that the locality should spend a great deal of money in entertaining it, although if men possessed money why should they not spend it in entertaining their friends. If he went to visit a lord, and the lord chose to entertain him in a manner suited to his position, he did not complain, and if he went to visit a peasant, and that peasant entertained him in the position in which he lived, he did not complain either, but he enjoyed the hospitality of the peasant as he enjoyed that of the lord. The was the true English spirit of hospitality. He was not reflecting on their friends at Ipswich, who had been deterred, no doubt, by the various little things which a host did for his friends, but those little things need not entail more than a fraction of expense. He put that plainly, and he hoped it would brush away any misapprehension with regard to the future of the Conference, and enable the smallest village where a hotel or lodging accommodation for 200 or 500 people because he hoped the numbers would rapidly increase, and that thing must be considered—but any community which could entertain the British Association, which required a guarantee fund of something like £2000 and sent a number of members, varying from 500 to 2500, into its neighbourhood would entertain them. It was a mere bagatelle. Whether it took place at the same time was a different point, and that difficulty had been solved in the present occasion. Their friends at Bournemouth would forgive him for saying that, because in the interest of the Conference he thought it had to be done so, but he had the greatest pleasure in seconding the motion. If he were not President at Oxford he had the choice he should like to be President. The Conference went to Bournemouth, for through the kindness of one of the past presidents he had an opportunity of spending a few days there, and he could assure them it was a most beautiful place. If they could only have the meeting when the rhododendrons were in bloom, they would see a sight which would make them love their native countryside, and renew their early affections for the beautiful scenery of England, but he had not the slightest doubt that what he saw in February, that at any time if it was a beautiful place, and he was perfectly sure they would be welcome there, whether the meeting was in the summer or in winter.

The motion was put and carried unanimously.

Mr. Bridge returned his hearty thanks for the compliment which had been paid to Bournemouth. If all the talk for the Friday excursions returned to the quarters they would have a fairly warm time, but he did not wish to prevent them doing so, because more they were the merrier they would be, and Bournemouth was big enough for them all, and great many more.

**Election of Officers.**

Mr. Naylor read the following list of officers who had been nominated by the Executive Committee:

- **President**—N. H. Martin, Newcastle-on-Tyne.
- **Hon. Treasurer**—John Moss, London.
- **Auditors**—C. Clayton, Oxford; F. Spinney, Bournemouth.

**Local Secretary**—Stewart Hardwick, Bournemouth.

The President said if there was no object offered, the gentlemen named would be elected, the
was quite open to any member to challenge a ballot, or to propose another president.

No objection being offered, the above were elected unanimously.

Votes of Thanks.

Mr. GROVES moved "That the hearty thanks of the meeting be given to the governing body of Christ Church for the use of the hall for the purpose of the reception by the President of the Pharmaceutical Conference." They then passed all for what a pleasure it was to visit that noble hall, and to have an opportunity of inspecting the various portraits which adorned it. They answered their purpose admirably, and they were all pleased to spend an evening there.

The resolutions were rightly due to the authorities, and the meeting especially to Mr. Balliol College for its address of welcome, and those who kindly provided the objects of interest.

Mr. JONES seconded the motion. The President, in putting it, said it was a work of immense perseverance to commend the motion to the meeting, and for some real attention to the warm reception given them by Canon Ince must have been very unpleasant to every one.

The resolution was carried by acclamation.

Mr. CARRINGTON moved "That the best thanks of the Conference be given to the Warden and Fellows of New College for making the afternoon available, and to all in their gardens. The observations one had to make with reference to these votes of thanks were necessarily much the same at every meeting of the Conference, but there was something special on this occasion, for such a number of their brethren had seen what he had known for a long time personally, that this great city, the beauty of its colleges, and its wonderful associations with it and its professors, whether in medicine, science, or divinity, were sympathetic with pharmacy.

Mr. Ince had great pleasure in seconding the resolution. It was one of those subjects on which it was not necessary to enlarge, and it was useless to attempt anything like praise, the beauty of the grounds and colleges of Oxford were too obvious to need reference, and he should just like to mention for one moment the perfect way in which the music on Tuesday afternoon was done.

The vote was carried unanimously.

Mr. ATKINS said it was with extreme pleasure that he moved the resolution which had been placed in his hands, for whilst they had much to be thankful for, weather, an excellent President, a good address, and hospitalitv, they had now specially to thank the Master and Fellows of Balliol College for their hall during the visit of the Conference.

It was a motion which needed nothing to commend it. They had had a warm welcome by the Master of Balliol, and they had the continued presence of the late master, whose beautiful trait had been his hospitality, and that the Master and Fellows of Balliol College had shown them their hall during the visit of the Conference. He should like to mention for one moment the perfect way in which the music on Tuesday afternoon was done.

The vote was carried unanimously.

Mr. CROSS moved "That the cordial thanks of the meeting be given to the real committee, especially to the President, Mr. Prior, the Secretary, Mr. Henry Mathews, and Mr. G. C. Duce, for the very successful manner in which they had carried out the arrangements for the Oxford meeting." The success or otherwise of the visit of a conference to a town was in exact proportion to the way in which the local committee forwarded the arrangements, and as they all felt that their Conference had been a great success in Oxford, it followed that these gentlemen had the thanks and made the best arrangements possible. It was a source of great satisfaction to those who came from all parts of the kingdom to feel the honour in which pharmacists were held, even at one of the chief seats of learning; that rooms like that were placed at their disposal, and men of high calibre could welcome them.

Mr. NAYLOR seconded the motion. He said he had been deputed to do so because he might, perhaps, have some little sympathy with the gentlemen who had undertaken these labours, more especially the secretarial duties. It had been his pleasure to be in constant correspondence with Mr. Mathews, not only in connection with the arrangements, but in connection with their work, and he could form some idea of the magnitude of his work, and knew that he had devoted himself to it most loyally and enthusiastically. Those in London knew Mr. Duce better than Mr. Mathews, and they all had a proof of the fact that he had assisted on several occasions, and no doubt the distinguished chairman of the local committee had also been of great help.

The President said he came to Oxford three months ago, when he first met the genial chairman of the committee, and spent a very pleasant evening. He was next conducted by Mr. Mathews round the various colleges and halls to advise which would be suitable, and practically he believed the whole of Oxford would have been available if they had required it.

The motion was carried by acclamation.

Mr. FIOX said he must disclaim any credit due for the arrangements which had been made, as he had very little to do with them after the invitation had been sent, the main part of the work being done by Mr. Mathews.

Mr. Mathews, on behalf of the committee, thanked the Conference for the kind manner in which they had received the arrangement, and for undertaking the duties of local secretary he felt he was undertaking rather a big task, as he was a stranger to the requirements of the Conference; but he felt that Mr. Thompson, his esteemed friend, and perhaps Mr. Clayton, would assist him, and they had very greatly helped him. And many of the members of the craft had not been active members of the committee, he could assure the Conference they had their sympathy. Many of them were in a peculiar position, being single-handed, and unable to leave their business, but this had given him an opportunity of calling on them, and they had all with one accord given their hearty welcome, expressed their sympathy with the Conference, and the majority promised pecuniary support, should it be required. He hoped that would not be the case. He thought that meeting at Oxford had been the inauguration of a little different system, inasmuch as it was particularly requested that they would endeavour to carry out the arrangements so that the Conference should be a self-supporting institution. 'In the early stages of his arrangements he was somewhat grieved to hear several remarks made in different parts of the country that many friends were called upon to give subscriptions to support the Conference, and did not pay their expenses. He felt this was wrong, but the Conference did not require it. He hoped they would be able to show that the Conference could pay its own expenses, and go where it liked, without being tied to anyone. This would
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS.

September 1, 1869.

give the Conference the opportunity of visiting smaller towns and cities. Oxford was a very small place to what it had been in the habit of meeting in, and he was sure their visit would be appreciated. A fellow townsmen told him that he was not inviting such an immense number of people to the town, as it must do a great deal of good. He thought they must do good not only to the town which they visited, but immeasurable good to themselves, as it brought the members of the craft in small towns out from note dull, miserable lives of their ordinary lives.

Mr. Bruce said he told them at Nottingham that he felt very much of an impostor. That feeling had not quite left him ever since he gave them such a warm invitation. It was not received with the enthusiasm with which he gave it, but he felt still more of an impostor now, because of this vote of thanks, in which he really had no share. Circumstances over which he had no control prevented him doing any work before the meeting, but it had undertaken a very laborious work, and had carried it on with a very successful way. Since then he had been there he had been engaged in doing what he could to make up for past neglect, and anything that he had done had been a labour of love.

The President wished to point out, in case something which fell from Mr. Mathews might be misunderstood, that the Conference had always been prepared to pay its own expenses; the members all paid their travelling and hotel expenses, but it was impossible to calculate such little items as printing and other things, and there must be a margin on one side or the other. At Oxford, as Mr. Mathews had told them, they had made arrangements which, it was hoped, would prevent the margin being, on the wrong side. If in some places the local people had spent money, it was not the fault of the Conference at all.

Mr. Reynolds said he had now to discharge a duty which he wished was in the hands of someone who could do greater justice to it. The Oxford meeting had been undoubtedly one of the greatest successes of the Conference. They had travelled for thirty years over the length and breadth of the land, and had received a welcome wherever they had gone, but they had never been more fortunate than they had been at that meeting. Perhaps one reason was that Oxford was not the country place of old days of Englishmen, it was the property of them all. It was the first and greatest seat of learning in England. From the days of Alfred it belonged to English men and women. As they looked over the streets of the city to-day, they saw that they were determined that England should command its wealth. The tension movement showed how wide the sympathy of Oxford was at present. Surely they had been extremely fortunate in meeting there. He did not wish, however, to travel over the ground occupied by previous speakers, his concern was to express on behalf of the meeting how well satisfied they were with the conduct of the President. There had been instances in which the President would certainly not forget—the welcome of the Master of Balliol, the presence of Sir Henry Acland, and the cordial way in which he recognised the relation between medicine and pharmacy, and the President, on his behalf and their own, accepted that position with a dignity which was creditable to the Conference. There was a danger in having a President so intimately connected with those more modern branches in connection with pharmacy and medicine, so that he was eminently the right man in the right place on such an occasion. He therefore begged to move “That this meeting recognises with the President, on whose behalf and their own, accepted that position with a dignity which was creditable to the Conference. There was a danger in having a President so intimately connected with those more modern branches in connection with pharmacy and medicine, so that he was eminently the right man in the right place on such an occasion. He therefore begged to move “That this meeting recognises that Mr. Martin had conducted its business, and accords to him a hearty vote of thanks.”

Mr. Martin had great pleasure in seconding the motion. They all had great respect for the President, and only regretted that he had suffered a great deal of loss of voice, which must have been a very great disappointment to him, but they were very much interested to hear the speech. They knew his character pretty well, and he had kept them thoroughly alive, and during the meetings. They knew his character pretty well, and he kept them thoroughly alive, and they had no doubt that he would have the same effect upon them at their ensuing meeting at Bournemouth.

The vote was carried by acclamation.

The President had a voice he did not think he could tell them how much he appreciated the honour of receiving this vote of thanks. But if he had a voice he did not think he could tell them how much he appreciated the honour of receiving this vote of thanks. But if he had a voice he did not think he could tell them how much he appreciated the honour of receiving this vote of thanks. But if he had a voice he did not think he could tell them how much he appreciated the honour of receiving this vote of thanks. But if he had a voice he did not think he could tell them how much he appreciated the honour of receiving this vote of thanks. But if he had a voice he did not think he could tell them how much he appreciated the honour of receiving this vote of thanks. But if he had a voice he did not think he could tell them how much he appreciated the honour of receiving this vote of thanks. But if he had a voice he did not think he could tell them how much he appreciated the honour of receiving this vote of thanks. But if he had a voice he did not think he could tell them how much he appreciated the honour of receiving this vote of thanks. But if he had a voice he did not think he could tell them how much he appreciated the honour of receiving this vote of thanks. But if he had a voice he did not think he could tell them how much he appreciated the honour of receiving this vote of thanks. But if he had a voice he did not think he could tell them how much he appreciated the honour of receiving this vote of thanks.

Mr. Martin had great pleasure in seconding
POISONING CASES AND INQUESTS.

THE USE OF INFANTS' POWDERS.

At the resumed investigation on August 22 into the circumstances attending the death of Bernard Reese (C.), late of 10, Hordern Road, Whitmore Reans, Wolverhampton, before Mr. A. B. Smith, deputy coroner, Mr. J. W. Scott, medical practitioner, of Milton Street, stated that he attended deceased when he was suffering from convulsive fits, probably due to teething. Shortly after ten o'clock on Monday morning he was called to see the child, but when he arrived he was very ill. He recommended to the mother that she should not give the child a powder, and said that it was very likely that it might have been poisoned. He had since made a post-mortem examination of the body.

Death was ascribed to tubercular disease of the mesenteric glands, accelerated by the administration of a powder, the elements of which were of too high a character to be safely administered to an idiot with such a disease. There was no outward show to show that the powder was a dangerous one.

The coroner considered the powder to be a dangerous one, and ordered that the same should not be administered without the advice of a medical man as to its health and constitution of the child.

Arthur Reade, chemist and druggist, and William Reade, laboratory manager at Reade Brothers and Co., put in the recipe for the manufacture of the powders. Each powder was 7.5 grains in weight. The ingredients were weighed by witness personally, and the best known was used to ensure a proper mixing.

Charles Randall, grocer, of 38, Coleman Street, deposed to selling the powder at midday on Sunday to Mr. Reese. He purchased the powders from Reade Brothers and Co., and had sold a great many of them, and had received no complaint about them.

Questioned by Mr. Reade, Dr. Scott said that if the child had not had the powder it would not have died on Monday. Most likely it would have died if it had had the powder, but it might have lived for weeks afterwards.

Mr. Reade: I don't want it to go forth that the powders are unsuitable for children as they stand generally.

Dr. Scott: I say they are.

Mr. John Allen Lyoest, medical practitioner, was introduced by Mr. Reade, and said he thought in some respects Dr. Scott was right, but in others it was all wrong. He thought it a good aperient for a child, but he knew with Dr. Scott that it was an improper powder to give to a child suffering from tubercular disease of the mesenteric glands.

The Coroner: With regard to a generally robust child, you don't consider it dangerous?

Dr. Lyoest: From the condition of the child, no doubt it would be injurious, but the powder itself I don't consider injurious. The mistake was in treating the child without having advice. As an aperient and given to a child in robust health, it would not be an unsafe powder.

The jury recorded the verdict that deceased died from tubercular disease of the mesenteric glands, accelerated by a powder containing elements of an unsafe character, and that there was no knowledge of its nature. No blame was attached to the mother, but caution should be taken by persons in administering the aliment to their own children. It was dangerous to purchase and administer what might be called "patent medicines" without advice from a medical practitioner.

Death from Alleged Use of Noxious Drugs.

At the Walthamstow mortuary, on August 22, Mr. C. C. Lewis, Coroner for South Essex, resumed his inquiry into the circumstances attending the death of Mary Ann Irish, aged 88, the wife of an optical case maker, residing at 42, Greenford Road, who died on Sunday, the 22nd of July last, from, it is alleged, the effects of taking noxious drugs (see ante, p. 160). Frederick Irish, the husband, stated that they had been married eleven years. The deceased was taken ill by vomiting about a fortnight before her death, but he did not call in any medical man. She was treated by a Mr. Wilson, a chemist. When the deceased was taken ill she admitted to the witness that she had taken drugs to bring about a miscarriage. The witness knew that she had a miscarriage on the 11th. The deceased told the witness to go to Mr. Wilson and tell him what had happened. Mr. Wilson called and saw the deceased the same day, and came nearly every day afterwards. In reply to the Coroner, the witness said the deceased first took her bed on the 11th. Richard Wilson, who had been acting as locus tenens to Mr. Andrews,* chemist, of 94, St. Mary's Road, Walthamstow, said the deceased first called on him about the 10th of July. On one visit she complained of violent sickness, and the witness made her up a bottle of medicine. It contained nothing injurious. The deceased told him that she had been taking something to bring about a miscarriage.—By the Coroner: After the deceased told him that she supplied her wife with a medicine, it did not supply her with the same as she had been taking. The witness further said he had called on the deceased in a friendly way, and not as a medical man. When he found the deceased was getting worse he advised her to call a doctor or to go to the hospital. He never led either the deceased or her husband to suppose that he was a medical man. Dr. Edward Cornwall, of 208, High Street, Walthamstow, deposed to being called about 10.30 on the morning of July 22. He found the deceased in bed unconscious, and in a moribund condition. She died shortly afterwards. The witness had since made a post-mortem examination of the body and found a very large amount of intestinal inflammation. There was evidence of the deceased having recently miscarried. The cause of death was suppurative periostitis and acute suppurative inflammation. Drugs which the deceased was said to have taken would produce this state of things. By the Coroner: Was it clear to you from your observation that she was in earlier, or when the miscarriage took place, she might have recovered, and her life have been saved. The jury, after a short consultation in private, returned a verdict in accordance with the medical evidence, and added a rider that in their opinion the husband should

* This name does not appear on the Register of Chemists and Druggists for 1894 with the address mentioned.
be severely censured for not seeking medical advice for his wife before he did, and further that he was greatly to blame in not attempting to prevent her from taking those drugs. The jury further added that Mr. Wilson, the chemist, was also deserving of censure for supply-
ing the deceased with drugs after knowing her con-
tdition. The Coroner, in censuring the husband, said that he entirely concurred with the expression of opinion by the jury that had the husband had any proper regard for his wife he would have acted differently, and probably might have saved her life. The police could now make further investigation, and if anything illegal had taken place, the Treasury could take the matter up.—Morning Advertiser.

Reviews and Notices of Books.

THE NATURAL HISTORY OF PLANTS. By Kerner and Oliver. Parts 4 and 5. Pp. 337 to 448, and 449 to 560, with woodcuts and coloured plates. Each part 2s. 6d. nett. London: Blackie and Son.

With the issue of part four the first half-volume is completed. Continuing the consideration of the form and position of the transpiring leaves and branches, attention is next given to transpiration during various seasons of the year, the fall of the leaf, the connection of the structure of the vascular tissues and transpira-
tion, and the conduction of food-gases to the places of consumption. The following section is devoted to the study of the formation of organic matter from absorbed inorganic food, and the distribution of leaves on the stem, etc., concluding with descriptions of the means by which leaves are protected against the attacks of animals.

In part five the study of metabolism and the transport of materials is introduced. Commencing with the compounds of carbon, the peculiar chemical properties of that element are first explained, with a view to showing that its nature is such as to admit of its union with other elements in inexhaustible combinations. It thus appears as the centre of all organic compounds in plants, and the materials of which the almost infinite multiplicity of these substances are formed are extremely simple, the changes undergone depending entirely upon the insertion and rejection, on the grouping and arrangement, of the atoms of a few elements. The albumins, cellulose, starch, diastase, pigments, and other cell-contents are then separately described, after which mechanisms for conveyance to and fro are considered at length. Respiration, the development of light and heat, and fermentation next receive attention, and the following section deals with the condition and mechanics of growth. The numerous phenomena included under this head are described and explained in a clear yet scientific manner that cannot fail to commend itself to all classes of readers, and the application of physical methods will throw a new light upon the subject to such botanical students as have not previously realised the close interdependence of the natural and physical sciences.

Thus, in dealing with the estimation of the heat necessary to growth, it is suggested that it should be possible to apply the mechanical theory of heat—according to which all motion can be converted into heat, and measured as such—to the phenomena of growth. "If it were practicable to determine the quantities of heat, which might be called the 'thermal constants of vegetation,' we should be able to estimate beforehand from the heat conditions prevailing in a particular place, whether this or that plant seed would thrive, whether it could produce ripe fruits, and whether or not its cultivation would be advantageous and worthy of encouragement." Some interesting results have already been obtained in this direction, with regard to the temperatures at which germination occurs in spores and seeds, and the length of time seeds must be exposed to the given temperature in order that the embryos should increase and develop. "If a hen's egg is exposed for only two or three days to a temperature of 35° to 40°, it will not be hatched; hatching can only take place if the egg remains for twenty to twenty-one days under the influence of this constant tempera-
ture. With seeds the case is the same. . . . If the num-
ber of days is multiplied by the temperature, the product may be looked upon as an empirical formula for the heat necessary to the process of germination. It must be considered that this product is of regular amount and it is regarded as a 'thermal constant.'" A table is then given, showing a selection of constants ob-
tained from observations extending over many years in central Germany, and referring to the issue of foliage leaves from the buds, the opening of the flowers, the ripening of fruit, and the commencement of leaf-fall. The reproach that botany is an insipid science is thus shown to be gradually but surely being removed, and it may be added that the interest of the subject is also proved to be immeasurably out-weighted by the frequently alleged dryness; this, however, being truism of all science when studied practically as with a proper desire to solve its problems in a systematic manner.

ANATOMISCHER ATLAS DER PHARMAKOLOGIE UND NÄHRUNGSMITTELKRÄUTER. By Dr. A. Techin and Dr. O. Oesterbll. Parts 3 and 4. 1s. 6d. nett. London: Williams and Norgate.

A careful inspection of parts 3 and 4 of Dr. Techin's Anatomical Atlas will undoubtedly convince any physician that they stand in no way inferior to the preceding parts, a notice of which has already appeared in the pages of this Journal (vol. iii., p. 599). A special interest to English pharmacists amongst the drugs dealt with are elder flowers and fruits, clown with clove-stalks and mother-clove, anise, fennel, Indian hemp, poppy capsules, poppy seeds and opium, coffee, sweet flag, and the leaves of various species of Mentha. Each of these is examined in a most exhaustive—It might almost be said too exhaustive—manner. In the article on the clove, for instance, separate organ present in the drug, viz., receptac-

ovary, ovule, calyx, corolla, stamens, and style, is
jected first to macroscopic examination, and then to microscopic examination. The latter is most minute and accompanied by useful hints as to the most suitable method of conducting the examination. The structure of clove-stalks and mother-cloves is described.
Novel Appliances and Apparatus.

A SAFETY INHALER.

This inhaler, manufactured by Messrs. Lynch and Co., is specially intended for use in chemical factories, drug mills, distilleries, manure works, and other places where the atmosphere is noxious, being so constructed as to filter the air before passage to the lungs, and thus neutralise any danger in inhalation. It will also probably be found effectual in bronchial disorders, phthisis, etc., etc. Being made of malleable metal, it may be readily adapted to the face, and is fitted with an inflated india-rubber cushion, which renders it perfectly airtight. By removing the cap the filtering sponge may be withdrawn and cleaned as often as desired.

Lynch's Perfection Safety Inhaler.

The Anti-Diphtherite.

A kindred appliance, the anti-diphtherite, supplied by the Sanitas Company, Ld., is intended as a safeguard for doctors, nurses, and other persons exposed to infection. A sponge is soaked in some disinfecting fluid and placed in the pouch A provided for its reception. The tubes are then passed over the head, the mouth-piece B is placed between the teeth, and the clip, which is so constructed that by adjusting the position of the staff the nostrils are securely compressed, closed. The air is thus inhaled solely from the back, and passes through a disinfecting medium of sponge. When not in actual use it hangs on the shoulders, and can be instantly adjusted when required.

POISON ALARM SIGNAL.

This is a simple and effectual preventive of accidental poisoning which has already been referred to in the Journal. It consists of a bell attached to a cork, which tinkles when the latter is removed from the bottle, just enough to warn the nurse without disturbing the patient. The patentee of this ingenious contrivance is Mr. Edwin J. Orchard, chemist, Salisbury.
Oblitary.

Notice has been received of the death of the following:—
On June 18, George Fawcet Dodds, Chemist and Druggist, Dunedin, late of Kelso. (Aged 65.)
On August 5, Philip Young, Chemist and Druggist, Castleford. (Aged 24.)
On August 9, Henry Nuttall, Chemist and Druggist, Lowton. (Aged 69.)

Correspondence.

INQUEST AT WOLVERHAMPTON.

Sir,—I beg to draw attention to your note headed “The Use of Teething Powders,” in the Journal for September 1, from which very serious inferences may be drawn and injury done, if not referred to. In the first place the powder was not a teething powder at all, nor recommended for any specific ailment, but an aperient powder for children from two to three years of age, as stated on the label. Furthermore, in evidence, it was stated by Dr. Lewis, one of the most experienced physicians in the town, that the composition of the powder was good, and not in any way injurious to a child of ordinary constitution, but that any aperient medicine would have been dangerous given to a child suffering from tubercular disease of the mesenteric glands. Lastly, the dose of each ingredient was well under the official dose, and the combined ingredients only a mild dose.

Local Secretary for Wolverhampton.

EMPIASTRUM LYTTE, P.B.

Sir,—In reply to Mr. H. H. Mason, I would suggest that the essence of disappointment in the use of empiastrum cantharidic is most likely to be found in the indifferent way in which the “blister” has been applied. Unless instructions be given it is often carelessly put on, and is, in all probability, not in contact with the skin. The centre of the “blister” should be first applied; it should then be firmly smoothed down with the hand towards the margin—this is especially necessary if the part to which it is applied be in the least degree covered with hair. In the course of my experience I have never had a complaint of the inefficiency of this plaster. If the blister be applied upon adhesive plaster, that upon unglazed calico should be used, as it adapts itself more readily to an uneven surface than the stiffer glazed material. Only a narrow adhesive margin should be left to save the patient much blister. When the plaster is removed, probably some persons are more easily affected by counter-irritants than others, owing to difference in temperament; but this question lies outside the domain of pharmacy.

Chesterham.

JOHN FLETCHER.

Sir,—Disappointment has been frequently experienced with regard to fresh samples of empiastrum lytice. This is the only official preparation containing cantharides in substance, and it seems to require time for complete diffusion and absorption. A striking illustration of this was furnished some time ago by the rejection of several blister papers but by a well-known druggist of which we declared to be ineffective; they had been dispensed with fresh made blister-plaster. In this dilemma, a supply of plaster which had been kept in stock was obtained from a wholesale house, with entirely satisfactory results. The same was originally rejected after month’s keeping to be equally serviceable, and in consequence no recently prepared empiastrum lytice ever afterwards allowed to be used for dispensing purposes.

Joseph Brox.

A QUERY SUGGESTED BY MR. DUDGE’S PASSAGE.

Sir,—I was reading in the Journal for September 5th a most valuable and scholarly paper read by Mr. Druce at Oxford, and the thought occurs to me of inquiring whether individual exists in Banbury now, as described by Drunken Barnaby’s itinerary:

“....in my progress travelling northward, Taking my farewell o’ th’ southward, To Banbury came I, O profligate one! Where I saw a Puritan one Hanging of his cat on Monday, For killing of a mouse on Sunday.”

I take it that many generations of Englishmen have ridden cock-horse to its famous cross, now, I think, no longer existent, and is there a child, to say naught of grown-up who doesn’t enjoy a Banbury cake?

J. BURZ.

COCO-NUT STEARIN AS A BASIS FOR SUPPOSITORY BACS.

Sir,—Having through unavoidable circumstances been prevented from attending the meeting of the British Pharmaceutical Conference at Oxford to read my notes on the above subject, I shall be glad if you will permit me to reply briefly through your columns to some of the remarks made therein, as reported in your issue of September 1st. Mr. Martin seems to have somewhat misunderstood the object of the paper, and father me with several suggestions which apparently he had made to his own imagination. He stated “he was sorry to see any suggestion that the basis in the B.P. should be altered.” I made no such suggestion in the paper, an object in introducing the subject being simply to bring the proposed base under the notice of pharmacists being one worthy of attention. He further remarked that “cocoa butter did not become rancid, and did not chafe by keeping,” an assertion, I venture to think, few will agree with. From personal observation I have noted whatever to do with pharmacy” (f.), and “who would go into the fractions of decimals that would show the difference between twelve stearin suppositories and twelve with cocoa butter?”—he again is evidently mistaking my meaning. They were, I presume, called forth by my statement that the coco-nut stearin base had the advantage of being cheaper, and could be made at one-third the cost of cocoa butter—a fact, which I still hold, would be of the consideration in large hospitals and other institutions where large quantities of suppositories are used. I am hardly say I am fully aware that cocoa butter is an ideal base for suppositories, and did not attempt to suggest otherwise. I quite concur with the comments made by Mr. Gerrard, and should assume the coco-stearin of “beautiful yellow” colour he experimented with must have been an impure variety, or else artificially coloured. I am therefore quite sure that the sample of the coco-stearin base with the Conference meeting, which was made over two years ago, and gave no signs of rancidity until eighteen months after making.

Liverpool.

Pharmacy as a Profession.*

BY DR. OSCAR OLDENBERG.
Dean of the Illinois College of Pharmacy.

A retail druggist who content to carry on a purely mercantile business, trafficking in all kinds of merchandise, is not a pharmacist, and he has no right to complain if he is subjected to the same inescapable competition which grinds all shopkeepers. The only part of the druggist's business which is valuable is the technical work he does. The plain truth of the matter is that a retail druggist is relieved from purely commercial competition just so far as he can demonstrate that he is a scientifically educated technical expert entitled to professional fees for his professional services, and no farther. This he can never do without being an educated pharmacist, and the more thoroughly educated he is, the better.

The assertion so often heard, that the public and the medical profession do not sufficiently appreciate the value of special education in pharmacy to discriminate in favor of his professional skill and services, and the only direction in which relief from the unfavourable effects of the excessive competition of the day may be found, points to increased knowledge, greater skill, and better service.

The question for you is: Do you want to be a retail merchant, or a half-educated apothecary, or a well educated pharmacist? If you wish to become a pharmacist—to make the art of pharmacy with all its related technical work your life pursuit—then your duty to the community you will serve, to the profession you propose to adopt, and to yourself, requires that you should fit yourself for that calling as thoroughly as your time and means will permit. And if you are enabled to acquire the education and training which are necessary to the intelligent performance of the technical work which an accomplished pharmacist is rightly expected to do, then you cannot be a pharmacist.

The Trained Pharmacist*

The pharmacist must be fitted to decide correctly in regard to the identity, quality, and purity of medicines, to combine and dispense them accurately, and to apply for these purposes the best means which scientific training affords. He should be practised in analytical methods, quantitative as well as qualitative, and in the use of the microscope, and grounded in the scientific principles as well as in the practical operations of pharmaceutical work. He should be equally well prepared for the best professional service at the prescription table, to aid the physician as the chemist of the medical profession, to act as public analyst, especially for the protection of health, to undertake the work of the manufacturing laboratory, or for any related technical pursuit.

The demand for technical services in these branches is increasing; the properly educated pharmacist or chemist readily receives just compensation for his professional skill and services, and the only direction in which relief from the unfavourable effects of the excessive competition of the day may be found, points to increased knowledge, greater skill, and better service.

All civilised countries have laws regulating the practice of pharmacy and the sale of medicines. Such laws are not enacted for the benefit of the pharmacists, but to protect the public against the serious dangers which threaten health and life when ignorant and unskilled persons are permitted to prepare and dispense medicines. The pharmacy laws of the world are becoming more stringent as civilisation advances. Persons without a medical education are no longer permitted to practice medicine, and persons without a pharmacist's education should not be allowed to practice pharmacy.

As the object of all pharmacy laws is the protection of the people against the evils of ignorance in an occupation which deals directly with powerful agents affecting health and life, it follows that these laws deal primarily with the enforcement of special pharmaceutical education. Experience has demonstrated that such compulsory systematic special training in pharmaceutical schools, even without any subsequent public examinations, insures satisfactory results, while the voluntary system of England and America has been found insufficient. Examinations are wholesome, provided the candidates are otherwise properly prepared by systematic courses of instruction in pharmaceutical schools.

England and America are well supplied with pharmaceutical schools, and it may be safely predicted that these countries will soon follow the example of others and prohibit the practice of pharmacy by persons not educated in pharmacy.

In the meantime public opinion will continue to demand higher education, greater technical skill, new duties and better service of the pharmacist; and he who is best prepared by education to satisfy this demand will enjoy the confidence of both the medical profession and the public. He who would succeed in any pursuit in this age must start upon a higher plane than that which was deemed sufficient in the past.

* Extract from an article in the Apothecary for August.

VOL. LIV. (Third Series, Vol. XXV.), No. 1264.

* Adapted from a pamphlet issued by the Northwestern University, Chicago, Ill.
The Beginnings of Chemical Study.

Chemistry is the subject which is generally considered to be the most difficult in the pharmaceutical curriculum, and rightly so, for in no other subject is a higher standard exacted in both the Minor and Major examinations. At the same time chemistry is the subject to which the pharmaceutical student is usually most attracted, and to the study of which he is prepared to devote most of his attention. This science assuredly holds the key to most of the mystery of the art of pharmacy, and the pharmaceutical student naturally regards it as standing to him in much the same relation as that in which anatomy stands to the student of medicine.

With regard to the amount of time which should be given to the study of chemistry, it is well to recognise at the outset that the standard now reached in the Major examination is such that the would-be pharmaceutical chemist must bear it continually in mind during the three or four years of study. In other words, if he wishes to have his work to be of appreception in the single year of systematic study at a school of pharmacy, which is all that the majority of students feel called upon to devote to preparing for the Society's examinations. For the sake of chemistry and the other science subjects of the curriculum, not less than for the sake of pharmacy itself, it is to be hoped that the days of apprenticeship in the strict sense of the word are drawing to a close. Even the essentials of the art of pharmacy can now only be properly learnt in the shop under very exceptional conditions, and it is a matter of common knowledge that the student of to-day, who has concluded his apprenticeship and wishes to pass the Minor examination, usually finds it necessary to learn a great deal of practical pharmacy and dispensing in the school where he spends at the most but one session, and has, in addition, to make chemistry, botany, and materia medica the subjects of special and detailed study. This, however, is a large and important question, and is only touched on here in order to guard the student against the idea that he can allow the study of chemistry to stand over until the term of his apprenticeship is completed.

He should, as far as possible, try to reach the ideal state of affairs, to which we are rapidly tending, when a three years' curriculum at a school of pharmacy will almost entirely replace the present system of apprenticeship and render it possible for the student of pharmacy to study during this period not only materia medica and the art of dispensing, but also the sciences of chemistry and botany. For the present, however, it must be assumed that the student is apprenticed in the usual manner, and will have comparatively little leisure for study, until he leaves for school or college. In occupying this leisure in preparing for the systematic study of chemistry later on, it is important that he should realise that he has to deal with an experimental science, which must be studied mainly in the laboratory. If he should happen to reside in a town where there is a college or institution in which these classes in chemistry are held, he is strongly advised to attend those classes including laboratory work, and each year to learn as much of the subject as he can in this way, sided by his own private study.

If, unfortunately, he should find himself out of the reach of classes, he cannot do better than invest in the first two volumes of the small work on 'Experimental Chemistry' which has been written by Professor Emerson Reynolds (Longmans), and perform for himself most of the experiments with the non-metallic elements which are described in the first volume. Then, if opportunity offers, most of the experimental work with the metals should be carried out, including simple qualitative and much of the more elementary analysis. He may be learnt if only the student will take pains to find out what chemical changes are occurring in each "test," and will make it a rule to write the simple equations which express these changes. Unless qualitative analysis is learnt in this way it had better not be learnt at all. There is no special merit in being able to "test" for the metals; it is easy for any little schoolboy to learn in the course of a few months or less, how to "find" the metals by noting the colours of precipitates.

The student's first point is to become well acquainted with elementary chemistry for general reference is Fisher's 'Class Book of Elementary Chemistry' (Clarendon Press), in which the properties of the elements and their compounds are accurately described in simple and straightforward language. The general principles of chemistry are very difficult for beginners to understand, and can only be learnt very gradually. In the majority of cases it is better to leave the attempt to master chemical theory until the last year of apprenticeship, when the student may begin to read the partly popular, but nevertheless accurate, account of the history of chemical theory which Mr. Pattison Muir has given in 'Heroes of Science, Chemists' (Society for Propagating Christian Knowledge).

Lastly, the apprentice is advised to avoid those literary productions on chemistry which are specially written and advertised for the pharmaceutical student. In many instances the erroneous ideas acquired by the student in his early days cling to him so pertinaciously that he finds it difficult to get rid of them even after he has been taught the truth. It is important to recollect that the first and foremost thing that the pharmaceutical student has to do is to learn the general facts and principles of chemistry as a science, so that he may be able to understand their applications in pharmacy, and afterwards to apply them himself in solving the problems which daily arise in pharmaceutical practice. This is the only true meaning of pharmaceutical chemistry.

Pharmacy at the present day needs all the help she can get from the science of chemistry, and chemistry can only be properly learnt so as to be useful by study and continuous work in the properly equipped laboratory of a public institution, under the supervision of a teacher who is thoroughly conversant with the modern developments of the subject. By following the lines indicated in the present article, the student will best prepare himself for this more systematic and directed course of study, without which the education of the pharmacist cannot be complete.
First Steps in Botany.

In commencing the study of botany, the student must remember at the outset that he is about to deal with living organisms, and all the details of form and structure which they present must be considered in their bearing upon the mode of life which characterizes the vegetable world. Everything that can be seen in a plant with the naked eye, or with the aid of a microscope, has some definite relation to the way it reacts to its environment, and can be explained accordingly. The first requisite for a successful student of botany is a power of careful and exact observation, and details which, to the novice, seem to have no particular purpose, are found on more extended acquaintance to play some part or other in the life of the plant on which they are found. Nor should a student be at all discouraged because the purpose of any particular part is not at once obvious. There are many mysteries about which nothing or next to nothing is yet known, but daily these grow less.

It is obvious from this that a student should not attempt to learn botany from books alone. The living organism itself should be his first object of examination. In the absence of a teacher to explain his difficulties, some book should be used side by side with the plant itself, but he must not fall into the error of thinking that owning the most complete acquaintance with the book can supersede actual observation and study of the plant.

In his first studies, such a book as Oliver's 'Lessons in Elementary Botany' (Macmillan) should be the first one used. Here he will find set forth what are the principal features which plants exhibit. Armed with such a companion, he should procure some simple wild plant and learn to identify its parts. Its outward form will first engage his attention, and the peculiarities of its root, its stem, and the appendages which spring therefrom should be carefully compared with the author's descriptions till he is familiar with the several parts. Then other plants should be taken and compared carefully with the first one and with the text-book descriptions. Thus he will form a good idea of the variety which each part of the plant is capable of showing. This variety will gradually lead him up to the idea of classification and natural relationship. The division of plants into groups and the sub-divisions of such groups can thus be grasped.

When this study of outward form and relationship has been carried on for a time, and only then, acquaintance should be made with the internal structure of the plant. It will be found that a close relationship between structure and habit of life is very easy to recognize. A water plant, or alga, whose life is spent under the surface of a stream or lake, has a very different amount of rigidity to one which lives on land, such as a herb or a tree. The sub-divisions of its body are different in the two cases, and its general consistency is not at all the same. The internal structure will be found to correspond to such differences—a tree will be hard and woody, difficult to cut or to tear, while a sea- weed will be succulent, and its interior delicate and soft.

Soon a microscope will be advantageously employed, and the minute details of structure can by its assistance be studied. Here another kind of text-book will be wanted; and no better can be placed in the hands of the student than Dr. Scott's little 'Introduction to Structural Botany' (A. and C. Black). A very simple plant, the wallflower, is the first one to be taken. It is a very common plant, and easily accessible everywhere. Again, no effort should be made to learn the contents of the book apart from the actual examination of the plant.

These two having been carefully studied, the student can turn to some more advanced text-book. By this time he will have formed a habit of working on the right lines, and can be trusted to pursue his studies more independently.

The work done so far will enable him then to take up the study of the vital processes which are carried on. The way plants absorb their food, what their food consists of, what changes are the result if such absorption, and so on, will be easily understood, and will at the same time illustrate and explain much of the detail already familiar to him. He will learn why the plant has assumed the form it has, and what is the meaning of the details of its anatomy.

The Principles of Pharmacognosy

The intelligent study of materia medica, or pharmacognosy as it is now more properly called, naturally presupposes a more than elementary acquaintance with the morphology and structure of plants. Without such previous knowledge it is difficult for the student to understand even the technical terms commonly used by lecturer and author in describing a drug, and quite impossible for him to have an adequate grasp of the subject he is endeavouring to study. And yet for him to possess such knowledge is the exception rather than the rule; the apprentice is frequently advised to commence his studies with materia medica; he does so by committing to memory the botanical order and habitat of the drug, and thus acquires a certain amount of parrot-like information which, when occasion may require, he repeats in a parrot-like manner, succeeding admirably in converting a fascinating study into tedious repetition. Should the student not be in a position to avail himself of the services of a teacher of botany, he would do well to take as his guide one of the many elementary text-books, and study morphology and structure on material that he can gather from field or hedgerow, for the commonest trees, shrubs, and herbs will furnish him with abundant examples. Such works as Lindley's 'School Botany,' Oliver's 'Lessons in Elementary Botany,' Scott's 'Structural Botany,' etc., will not only render technical botanical terms intelligible and familiar to him, but will train him to observe, and to observe critically; for this reason the necessity for making the subject essentially a practical one cannot be too strongly insisted on. Nor should he content himself with simply collecting and examining leaves and flowers, as is often the case. Roots, stems, and fruits should, and as his interest grows, would be subjected to scrutiny. Much information can be gained by allowing stems and roots to dry, and observing the changes that take place. At the same time, with the aid of a text-book his knowledge of systematic botany would grow without effort, and
the student would find himself in a position to study with advantage the crude drugs derived from the vegetable kingdom. In extending his studies in this direction he would do well to classify his drugs organographically, and study the most familiar, say the leaves, first. By this means the mental strain involved in constantly transferring the attention from one to some other totally different organ would be avoided, and the powers of observation further tested. Moreover, he should prefase the study of the leaves by studying in his text-book the structure of the leaf in general, and the same with the other organs.

In dealing with the vegetable drugs the aid of a text-book must be invoked. As the student reads the drug should be in one hand, his hand-lens in the other; that each statement as it is read may be verified or corrected, but he is advised to refrain from reading in his text before he can acquire a knowledge of botanical anatomy. From the 'Medicinal Plants' of Bentley and Trimen, if available, he will gather an idea of the appearance and habit of the mother plant, whilst the 'Pharmacographia' offers him in most attractive form concise accounts of its commerce and history. Thus, and thus only, can he learn to know a drug. Let him be warned against all tables of materia medica that contain little more than the 'name, natural order, and habitat' of the drug, and that may at most serve to 'cram' for examinations in which little else is required of the candidate, but bear about the same relation to materia medica as a box of dry bones does to the living creature of which they once formed a part. Let him also avoid the error, too commonly committed by both student and teacher, of reducing his studies to the mere discernment of certain characters by which one drug may be distinguished from others that resemble it. The desirability of his being able to so distinguish each and every drug is undeniable, but it is only a fraction of the object of his studies, and is certainly not the object which he is already acquainted if his examination of each drug has been minutely and conscientiously carried out. He should at all times distinctly remember that his business is not simply to know this or that detail in any one drug, but to be familiar with at least the leading points in the history, life-history, structure, and composition of every drug.

To understand the production and collection of structureless drugs obtained from plants the student must be acquainted with the various glands, ducts, lactiferous vessels, and other tissues in which such substances as oils, oleoresins, gum-resins, etc., are secreted by the plants, as well as the changes which cellulose may undergo in the formation of such substances as gum or resin. Here, necessarily, the microscope must be requisitioned for the study of these structures, and it may be assumed that the student will have made sufficient progress in anatomical botany to enable him to make an intelligent use of the instrument; certainly he will find the study of this second section of materia medica amply and explain much that he had read and observed in the first.

Nor will the study of these drugs be complete without an approximate knowledge of their chemical constituents, their chief reactions, and principal physical characters.

Up to this point the student has been dealing with drugs more or less intact; the further development of the subject will logically consist, first, in the identification of unknown, fragmentary, or powdered drugs, and, secondly, the micro-chemical detection of their active principles and determination of the tissue or tissues in which they reside. A study which is best pursued at the hand of an experienced histologist.

Pharmacy and Dispensing.

The following remarks are an attempt to answer the very difficult question, what preparation in practical pharmacy and dispensing may a student profitably make before entering upon his college course? Let it be stated that it is hardly possible to set too high a value upon a well-regulated apprenticeship, may, even that the immediate gain to be expected from a three years' course in the proportion to a previous acquaintance with the various details, partly of a business character and partly chemical, which are essential to the right conduct of pharmacy.

Circumstances differ so widely that it would be unwise to lay down definite rules which should equally apply to all, but one thing is beyond doubt, that it is undesirable, generally, to let youth acquire his first knowledge of pharmacological operations from the class-room and the lecture or that his attendance at a public course should be his introduction to the art of despising a prescription and following out its instructions. It is to force him to read a book, ignorant of the alphabet which forms the words.

Let the tyro carefully consider his own surroundings, and say to himself, I have chosen pharmacy for my vocation, and if I may hope to be successful and not a mere shopman, I must know about the objects and appliances in the midst which I am placed, what they are, where they come from, and for what they are used. The young pharmacist will find a selection of drugs, simple apparatus, and preparations as are commonly met with in pharmacy; let the drugs be so persistently examined that their physical characters may become familiar, and they may be recognised without the label. Let careful examination of every description apparatus, if only worthy of the name of drug, be a fixed rule, and sundries, come next, while preparations may follow in due time. The end of the first year should be the apprentice's adept in measuring and weighing and in the mechanical art of powdering drugs and chemicals: he should be able to make an infusion and a decoction should not be beyond his skill.

At this point, Whitta's 'Pharmacy, Materia Media and Therapeutics' (Renahaw) will prove a serviceable guide.

Unfortunately the position of an apprentice who has not the chance of observing many and sundry operations relating to his craft; if wise, he will from the commencement of his career devote himself to their practical manipulation, and take pleasure in so doing. Should the task be distasteful, let him catch his want of interest, for unless he gets to like his occupation he will make but scanty progress. Once the desire not to be commonplace kindled, a striving to excel will be created, and he will learn slowly but effectually the whole
Elementary Pharmaceutical Education in Great Britain.

Educational Facilities in London.

The School of Pharmacy conducted by the Pharmaceutical Society of Great Britain was founded in 1842, as a means of providing a sound education in the scientific principles on which the practice of pharmacy is based, and has been consistently developed during the past half century by the Council of the Society, so that it has at all times afforded a complete scientific curriculum, for the time being, for pharmaceutical students. There are now separate departments, each complete in itself, of Chemistry, Practical Chemistry, Botany, Materia Medica, and Pharmacy, and apprentices may enter for any single subject during their period of pupillage. Chemistry, including Physics in relation to Chemistry, is taught by Professor Dunstan, M.A. Oxon., F.R.S., assisted by Mr. H. A. D. Jowett, B.Sc., and there are two distinct courses of lectures (the second for advanced students) delivered during the session. Instruction in the Chemical Laboratories, which are open daily, is directed by Professor Attfield, Ph.D., F.R.S., and Mr. F. W. Short, B.Sc., and here again there are both Junior and Senior Courses. The lectures on Botany, by Professor Green, Sc.D., M.A., deal, in the first course, with the Morphology and Anatomy of Plants, including the Vascular Cryptogams, and also embrace the leading facts connected with their Physiology and mode of life. In the second course, the phenomena of reproduction are considered in detail, together with the principles of classification and the peculiarities of the chief British Natural Orders. Classes in practical work are arranged as convenient, the study of plant histology by the aid of the microscope being a prominent feature. Materia Medica and Histology are in charge of Professor Henry G. Greenhaw, who, in addition to lectures, conducts demonstrations in the Histological Laboratory, whilst the Theory and Practice of Pharmacy are taught by means of lectures and demonstrations by Mr. Joseph Ince. Systematic instruction in Dispensing and Practical Pharmacy is afforded in the Pharmaceutical Laboratory. Students who have passed the Major Examination are eligible for admission to the Research Laboratory where, under the direction of Professor Dunstan, they may obtain instruction in the methods of research and undertake special investigations. The Society's Library, Reading Rooms, and Museums are all available to students who are connected with the Society. Applications for prospectuses and further information respecting the school should be addressed to the Secretary, Mr. F. W. Short, 17, Bloomsbury Square, W.C. Evening classes are not conducted as yet, but doubtless were there any demand for instruction by students engaged in business during the day, it could be provided. At the same time evening courses in most of the subjects are conducted at King's College, the Birkbeck Literary and Scientific Institution, the City of London College, and in connection with numerous other institutions in and about the metropolis.
Provincial Educational Facilities.

Aberdeen.
The Aberdeen and North of Sootland Society of Chemists and Druggists open their laboratories and museum in Bridge Street daily for practical work. Elementary Chemistry and Botany are taught at Robert Gordon's College. A class in Practical Chemistry is conducted at the Society's rooms, as well as others in Materia Medica and Pharmacy. Information concerning these classes may be obtained from the Secretary, Mr. A. Strachan, 138, Rosemount Place, Aberdeen. In connection with the Faculty of Medicine of the University of Aberdeen, classes are held in Inorganic and Organic Chemistry, Materia Medica, Botany, and Physics. The Chemical Laboratory is open daily, a Pharmacological Laboratory affords opportunities for research, there is a class for practical laboratory work in Botany twice weekly, and the Botanical and Materia Medica Museums contain extensive collections of specimens. Intending students must fill up schedules, to be obtained from the Librarian, Marischal College.

Aberystwith.
At the University College of Wales, Aberystwith, Professor Snape lectures on Chemistry, and the Chemical Laboratory is open daily. Special arrangements will be made for medical or pharmaceutical students, if required, the hours for practical work being arranged to suit individual requirements. Application should be made to the Registrar.

Bangor.
Lecture courses on Chemistry (Professor Dobbie), Physics, and Botany are conducted at the University College of North Wales, Bangor, and are recognised for medical and pharmaceutical students, if required, for the examination in the Universities of Edinburgh and Glasgow. There is a Chemical Laboratory also, open on five days of the week, for instruction in Chemistry Analysis and the Application of Chemistry to Medicine, etc. Particulars may be obtained from the Registrar.

Birmingham.
Students can profitably spend their first and second years at the Technical School, and the third at Mason College. At the Technical School there are Elementary and Advanced Courses in Inorganic and Organic Chemistry (Theoretical and Practical), Experimental Physics, and Botany. At Mason College the Chemical Lectures and Laboratory are under the control of Professor Percy E. Frankland, and Botany is practically and experimentally taught by Professor Hillhouse. Materia Medica and Pharmacy are in the hands of Mr. John Barclay, assisted by Mr. J. D. Whittles, and there is also a class in Chemical Physics, conducted by Professor J. H. Poynting, whilst the Herbarium, Materia Medica Museum, Pharmaceutical and Bacteriological laboratories are of great value in enabling students to acquire practical experience. Syllabuses may be obtained from the Secretaries of the respective institutions.

Bradford.
The Calendar of the Bradford Technical College gives particulars of Day and Evening Classes in Elementary and Advanced Inorganic Chemistry; Organic Chemistry, Theoretical and Practical; Qualitative and Quantitative Analysis; Botany, and Organic Materia Medica. The last two are conducted by Mr. William West, and are specially adapted to the requirements of pharmaceutical students. Laboratory practice may also be had at the College, and the fees are extremely moderate. Prospectus and other information may be obtained on application to the Secretary.

Brighton.
At the Municipal School of Science and Art, Brighton, there are several suitable classes for pharmaceutical students. Inorganic and Organic Chemistry are taught, both theoretically and practically, by M. Clutterbuck, B.Sc., Ph.D., whilst Botany, Materia Medica are also included in the syllabus, the teacher being Mr. H. Edmonds, B.Sc. The prospectus will be sent on application to the Secretary, Grand Parade, Brighton.

Bristol.
Evening courses are conducted at University College, Bristol, in Elementary and Advanced Chemistry, Chemical Physics, and Botany. The Botanical Garden is open to students to aid them in their studies. Day classes are held in Inorganic and Organic Chemistry, Experimental Physics, and Botany, the Chemical Laboratory is open daily, and there is also laboratory instruction in Physics and Botany. Materia Medica and Practical Pharmacy form part of the scheme of study in connection with the Faculty of Medicine of the College. Further information will be supplied by the Secretary of the College.

Cambridge.
The following classes will be held at the Technical Institute in connection with the Science and Art Department, commencing Monday, September 17th—Magnetism and Electricity (Mr. Heber Smith), Botany (Mr. A. Stubbs), Chemistry, with laboratory practice (Mr. F. Stokley). Fee for the course for any two subjects, 5s., except Practical Chemistry, 8s. The course is expected to last a considerable time. It is hoped that the local pharmaceutical association will be able to arrange for its members to use the Laboratory of the Technical Institute. There are excellent Botanical Gardens belonging to the University open to the public, where a great number of the official and official plants may be seen growing.

Cardiff.
At the University College of South Wales and Monmouthshire, Cardiff, there are lectures on Inorganic and Organic Chemistry (Professor C. M. Thompson), Qualitative and Quantitative Analysis, Physics, and Botany, and the Chemical Laboratory is open daily. There are also special classes of lectures on Chemistry, Physics, Materia Medica, and Pharmacy, in connection with the Faculty of Medicine. The Registrar will furnish a copy of the syllabus on application. Evening Classes are conducted at the Borough Technical School, in Physics, Inorganic and Organic Chemistry, with laboratory practice, at merely nominal fees. Application should be made to the Secretary for details.

Chester.
At the Chester School of Science and Art the Chemical Laboratory has been much extended, and
classes are held in Theoretical and Practical Chemistry and Physics (Mr. J. A. McMichael, B.A.) and Botany (Mr. J. D. Siddall). Laboratory practice in Physics has also been arranged. A copy of the prospectus will be sent on application to the Clerk to the Governing Body (Mr. C. R. Enoch), Grosvenor Museum, Chester. The Materia Medica collection of the Chester Chemists' Association is a very complete one, and together with the above classes is of great service to an annually increasing number of pharmaceutical students.

DUNDEE.

Classes in Chemistry, Botany, and Physics are held at University College, Dundee, and the laboratory instruction there provided is also suitable for pharmaceutical students. Particulars may be obtained of the College Secretary.

EDINBURGH.

Pharmaceutical students are admitted on special terms to certain of the courses of Lectures on Botany, Chemistry, and Materia Medica, and of practical instruction in Chemistry, recognised by the University of Edinburgh, and the Royal Colleges of Physicians and Surgeons, Edinburgh. At the Heriot-Watt College there are classes in Chemistry and Physics, with laboratory instruction in both. There are also Evening Classes in Theoretical and Practical Chemistry (Professor Gibson, Physics, and Botany (Mr. J. A. Thomson), with special arrangements for medical and pharmaceutical students in Practical Chemistry. Other classes in the same subjects may be attended at the University of Edinburgh, and special pharmaceutical classes (day and evening), in all the essential subjects, with laboratory instruction in Chemistry and Pharmacy, are conducted by Mr. William Duncan, aided by competent assistants, at the Royal Dispensary, under the control of the Board of Managers. The Pharmaceutical Society's Library, Reading Room, and Museum are at the service of all students connected with the Society. Full details may be obtained on application at the respective institutions, or of Mr. J. Rutherford Hill, Assistant Secretary to the Pharmaceutical Society, 36, York Place, Edinburgh.

GLASGOW.

Lectures are given on Chemistry (Professor Watson), Physics, Botany, and Materia Medica at Anderson's College, and the Chemical Laboratory is open daily. Similar arrangements exist at St. Mungo's College, where there is a well equipped Bacteriological Laboratory, and the practical work in Botany includes work with the microscope. Day and evening classes are also held at the Glasgow and West of Scotland Technical College, and special arrangements are made for pharmaceutical students in connection with the courses in Inorganic and Organic Chemistry, and Laboratory Instruction, held at the Grove Street Public School.

HOVE.

Classes in Theoretical and Practical Chemistry, in connection with the Science and Art Department, London, are conducted at Hove by Mr. H. Edmonds, B.Sc., at the Connaught Road School Laboratory. The fee for the theoretical classes is 2s. 6d. per term, and for the practical, 7s. 6d. per term, including the use of the necessary apparatus and materials. Special attention is given to pharmaceutical students. Application should be made to the Organising Secretary of the Science Classes, Connaught Road, Hove.

INVERNESS.

Arrangements are now almost complete in Inverness for providing suitable instruction for pharmaceutical students. Classes in Practical and Theoretical Chemistry, Materia Medica, Pharmacy, and Botany are being arranged in connection with the Burgh Technical School in Castle Wynd. A competent chemist is to conduct the classes in Pharmacy and Materia Medica, while the other teachers of the School will carry on the teaching of the remaining subjects. A class in Practical Physics is under consideration. It is hoped that students from the neighbouring towns of Nairn, Forres, Dingwall, Beauly, etc., may be able to take advantage of these classes. The Highland Railway Company is expected to afford facilities in the way of cheap tickets to those who come from a distance. In addition, the fees charged at the Burgh School are almost nominal. Any further information can be obtained from Mr. John Don, M.A., B.Sc. Lond., Science Master.

LEEDS.

In connection with the Yorkshire College, Leeds, there are Day Classes in Physics (Professor Stroud); Inorganic, Organic, and Applied Chemistry (Professor Smithells); and Elementary and Advanced Descriptive and Systematic Botany (Dr. J. H. Wilson). In addition, courses of practical work are conducted in the Physical, Chemical, and Biological Laboratories. There are also Evening Classes in Chemistry. Particulars may be obtained of the Registrar and Secretary. The Leeds School of Science and Technology, Rossington Street, Leeds, offers many advantages to students of pharmacy in the evening classes for the study of Elementary and Advanced Chemistry, Theoretical and Practical, and in Practical Physics, under the able management of the Head Master, Mr. S. J. Harris, M.Sc., with competent assistants, and also in Botany, taught by Mr. Tate, F.G.S. A prospectus may be had from the Secretary, Mechanics' Institution, Leeds.

LIVERPOOL.

At University College, Liverpool, there are day classes in Physics (Professor Oliver Lodge); Inorganic, Organic, and Physical Chemistry (Professor J. Campbell Brown); and Botany (Professor R. J. Harvey Gibson), including Morphology and Classification, Histology, Comparative Physiology, etc. Laboratories are open daily in the different subjects, as well as the Museum and Herbarium, to pharmaceutical students attending the appropriate lecture course in Chemistry, accompanied with five months' laboratory work. Evening classes are held in Physics, Chemistry (including Qualitative Analysis), and Botany. Applications should be addressed to the Registrar.

LYNN.

The new Technical School is capable of accommodating about thirty students in the Chemical Laboratory, one hundred in the Lecture Theatre, and
twenty-five in the Physical Laboratory, which is
fitted for the study of Heat, Light, Sound, Electricity, Magnetism, and Mechanics. There are evening classes in all science subjects. The fees are low, and there is ample scope for pharmaceutical apprentices to gradually obtain a thoroughly efficient knowledge of subjects connected with their calling.

MANCHESTER.

In the prospectus of the Pharmaceutical Department of the Owens College, Manchester, pharmaceutical students are strongly advised to pass the Preliminary Examination in Arts before entering on the College courses, and then to attend to the following lectures and practical classes:—Chemistry, Botany, Materia Medica, Pharmacy, and Pharmaceutical Chemistry, together with lectures on Pharmacy Law. For the advanced course, classes are arranged in Botany and Materia Medica (lectures and practical), and laboratory courses in Organic and Pharmaceutical Chemistry. Chemistry is taught by Professors Dixon and Perkin, Botany by Professor Weals and Mr. Hick, Materia Medica by Professor Leech and Mr. Kirkby, Pharmacy and Pharmaceutical Chemistry by Mr. Hoesoun, and Pharmacy Law by Mr. Kirkby. An entrance exhibition of £10 will be offered for competition in October, 1894, to students entering for the full pharmaceutical course. The subjects of the examination will be Elementary Botany and Chemistry. Candidates must give notice to the Registrar of their intention to compete on or before September 20. A scholarship of £10 and a prize of £5 will be offered at the end of the Winter Session (1894–5) for competition among students proceeding to the advanced course. The College Prospectus will be sent on application to the Registrar.

NEWCASTLE-ON-TYNE.

The North of England Pharmaceutical Association has arranged with the authorities of the Durham College of Science, Newcastle-on-Tyne, to conduct classes on similar lines to previous years, and the educational wants of pharmaceutical students are thus fully provided for. Both day and evening classes are held. Professor M. C. Potter will lecture on Botany, and there will be laboratory work on the same subject, practical instruction being given in dissection and the use of the microscope in vegetable histology. Chemistry will be dealt with by Professor P. Phillips Bedson, who will have several assistants in the laboratory to supervise the work of the students, the needs of pharmacy students being again kept prominently in mind. Mr. N. H. Martin will lecture on Materia Medica and Pharmacy. Though none of the fees are high, students who are connected with the local Association will be admitted to the Chemistry lectures at a reduced fee, and they will have in the Library and Museum of the Association, which are now located in permanent quarters in the handsome new buildings which have recently been added to the college. In addition to the above classes, during the Easter term a course of botanical excursions in the neighbourhood has been arranged, for the small fee of five shillings. These should be largely made use of by the young pharmacists of the district. Application for further information should be made to the Secretary of the Durham College of Science, Barras Bridge, Newcastle-on-Tyne.

NOTTINGHAM.

In order to afford facilities for obtaining special pharmaceutical education during apprenticeship, the Council of the Nottingham and Notts Chemists' Association has arranged for a three years' course of instruction, to be given at University College, Nottingham. The first year Pharmaceutical Chemistry and Physics are taught; the second year, Pharmaceutical Botany and Practical Dispensing; and the third year, Materia Medica and Organic Chemistry. During the coming session, arrangements have been made for a course of lectures and demonstrations in Pharmaceutical Botany, to be given by Professor Carr, M.A., and Mr. E. A. Smith. Elementary Structural and Physiological Botany, and Systematic Botany will be dealt with, and there will be practical demonstrations in the latter. The course will be fully illustrated by lantern-slides and microscopic and other preparations.

Reading.

At the University Extension College, Reading, classes are conducted in Chemistry and Physics (Mr. J. B. Austin), with laboratory instruction, and in Botany (Mr. B. J. Austin). Full particulars may be obtained from the Secretary.

SHEFFIELD.

All the classes conducted at the Sheffield School of Pharmacy, promoted and supported by the Sheffield Pharmaceutical and Chemical Society, are specially designed to advance the technical education of students in pharmacy. There are lectures on Botany and Materia Medica (Mr. J. Austen); Theoretical and Practical Chemistry (Mr. J. C. Plate); and there is a laboratory for practical work. The fees are low, and students are entitled to make use of the Library and Museum belonging to the Society. The Secretary of the School will answer any inquiries addressed to New Surrey Street, Sheffield. Classes in general Chemistry, Botany, and Physics are held at Firth College, Sheffield, where laboratory instruction in the various subjects may also be obtained. particulars may be obtained of the Registrar.

SUNDERLAND.

Classes in Theoretical and Practical Inorganic Chemistry (Mr. R. Richardson, B.Sc.); Botany (Mr. Wm. Fowler, L.S.A.); Sound, Light, and Heat (Mr. J. Hindmarsh); and Magnetism and Electricity (Mr. D. Woolasot, B.Sc.), are conducted under the Sunder-
Pharmaceutical Examinations.

MINOR EXAMINATION.*

This examination is the legal test of qualification for registration under the Pharmacy Act, 1868, as a chemist and druggist. Successful candidates share the exclusive right to this title, and to dispense and sell such poisons as are scheduled under the Phar- macy Act. They are entitled also to be elected associates of the Pharmaceutical Society and present themselves for the Major examination. The requirements demanded of each candidate are that he shall be registered as having passed an approved scholastic examination, as a test of elementary education and fitness to acquire the requisite technical and scientific knowledge; he must also produce a certified declaration that for not less than three years he has been practically engaged in the translation and dispensing of prescriptions; and, finally, he must be twenty-one years old at the time of giving notice. This notice must be given and the fee (£5 5s.) paid to the Registrar—Mr. Richard Brems- ridge, 17, Bloomsbury Square, London—not later than the fifteenth day of the month immediately preceding in which the examination is to be held.

The subjects of examination are prescriptions, practical dispensing, pharmacy, materia medica, botany, chemistry and physics, practical chemistry, and the law relating to the sale of poisons. A summary of the requirements is here given—

**Prescriptions.**—The candidate is expected to read abbreviated Latin prescriptions in full, translate and understand them, detect errors, discover unusual doses, calculate quantities, and render English prescriptions into Latin.

**Practical Dispensing.**—In this subject the candidate is expected to dispense medicines from prescriptions exactly as though he were working in a pharmacy. A special factor taken into account in awarding marks is the time occupied in doing the work.

**Pharmacy.**—A general knowledge must be possessed of the operations of evaporation, sublimation, and desiccation, and their practical application in pharmaceutic processes. The methods and apparatus used in the disintegration of solid substances, solution, filtration, and expression, must also be familiar, as well as the principles involved in the dispensing of medicines. Finally, the candidate will be required to possess a knowledge of the proportion of active ingredient or crude material in the more potent official preparations, as well as to show a practical acquaintance with the processes by which the following official preparations are made:—coatings, confections, decoctions, dilute acids, extracts, glycerins, infusions, juices, liniments, lotions, mixtures, ointments, pill masses, plasters, powders, solutions, spirits, supersol-
tories, syrups, tinctures, vinegars, wines, and wines.

**Materia Medica.**—Crude drugs, mentioned in the British Pharmacopœia, and a few non-official ones, must be recognised at sight, and their methods of pro-
duction and characteristics described. Candidates must also be familiar with the geographical sources of the drugs, their technical names, and natural orders of the plants and animals yielding them, their chief active constituents, and the official preparations into which they enter.

**Botany.**—A limited number of medicinal plants, mainly indigenous, must be recognised and referred to their classes and sub-classes. The internal structure of stems, leaves, and roots must be known generally, as well as the structure and contents of the cell. A practical acquaintance with the external morphology of plants is also required, together with a general knowledge of the processes of reproduction and the physiology of plants. Work with the micro-
scope includes the recognition of stem sections, the chief varieties of vessels, and structures such as stomata, pollen, and hairs.

**Chemistry and Physics.**—Candidates are expected to possess an elementary knowledge of the law of the conservation of energy, the law of gravitation, the British and metric system of weights and measures, the balance, specific gravity, atmospheric pressure, the barometer, air pump, and syphon, the law of Boyle, temperature, thermometer, the law of Charles, the law of gaseous diffusion, V. Meyer's method for determining vapour densities; the chief characteristics of chemical action, the distinction of elements and compounds, the laws of chemical combination by weight and volume, the hypothesis of Avogadro, atomic weight and molecular weight, chemical formulae and nomen-
clature, valency, the distinction between metals and non-metals. They must also be acquainted with the general characters of the non-metals, the chief methods of preparation and the typical reactions of a number of non-metallic elements and compounds, and the usual impurities in those that are included in the British Pharmacopœia. Further requirements cover the general characters and classification of the metals, and the general methods of forming oxides and salts; the sources, the usual methods of extracting, and the chief properties of various metals, and the principal modes of preparation, properties, adulterations, and contaminations of such of them as are described in the British Pharmacopœia; the chief methods of pre-
paring a number of carbon compounds, and a general knowledge of the methods of determining the carbon, hydrogen, oxygen, and nitrogen in organic compounds, and of obtaining molecular formulæ. Candidates will be expected to solve simple problems relating to the weight and volume, under different conditions of temper-
ature and pressure, of elements and compounds concerned in chemical reactions.

**Practical Chemistry.**—The syllabus includes the determination of specific gravities, familiarity with the general construction and use of the thermometer and barometer, the recognition by chemical tests of the more important non-metallic elements and com-

* A fully detailed syllabus of this examination will be found in the Calendar of the Pharmaceutical Society.
pounds, and several organic compounds, as well as to detect the chief impurities in the metals and salts included in the British Pharmacopoeia, and to recognize by their physical properties those which possess well-defined characteristics. Volumetric determinations as described in the British Pharmacopoeia must be performed, and candidates must be able to quantitatively determine the total alkaloids in cinchona bark, and in the tincture and extract of nux vomica, and the morphine in opium. They will further be expected to have a practical acquaintance with the methods of preparing the more important inorganic substances, including the non-metals and their compounds, and such metallic compounds as are included in the British Pharmacopoeia, as well as several organic compounds.

The Law relating to the Sale of Poisons.—Candidates will be required to enumerate the poisons contained in Schedule A of the Pharmacy Act, 1868, and those since added thereto. They will be required to describe minutely the conditions required upon the sale by retail of poisons, in Parts I. and II. of Schedule A; and to write the proper entry required, according to Schedule F of the Act, for the sale of a poison coming within Part I. of Schedule A. They will also be required to state the conditions imposed on the sale of scheduled poisons by wholesale and for export; and upon the sale of a scheduled poison when forming an ingredient in a medicine dispensed. A knowledge of the conditions imposed on the sale of arsenio by the Arsenio Act will also be required.

MAJOR EXAMINATION.*

Three months after passing the Minor examination candidates may present themselves for the Major examination, upon passing which they are eligible for registration as Pharmaceutical Chemists under the Pharmacy Act, 1852. Pharmaceutical Chemists are entitled to be elected members of the Pharmaceutical Society, and are exempt in England and Wales from service on all juries and inquests, under the Juries Act, 1862. The fee is three guineas, and the examination may be oral, practical, or in writing, the subjects being botany, materia medica, chemistry, and physics.

Botany.—In addition to what is required for the Minor, the candidate is expected to possess an intimate acquaintance with the parts of the flower, fruit, and seed; to describe the structure and development of the pollen, ovule, and seed; to have an intimate knowledge of the structure and contents of cells; and a general knowledge of the origin of gums, acids, and other secretions of plants. He must be familiar with the composition of the cell wall, and the changes it undergoes. A knowledge of the general principles of classification, the system of Linnaeus, and of the natural system founded upon that of De Candolle is required, as well as ability to distinguish practically a number of natural orders, and the lead-

* A fully detailed syllabus of this examination will be found in the Calendar of the Pharmaceutical Society.
The pharmacist as a chemist cannot afford to be ignorant of the higher mathematics, French, or German; his Latin and arithmetic ought to be above suspicion; and he ought to know his own language and be able to express his thoughts in writing much better than he usually does.

With regard to subsequent studies, full information is given in the different articles published in the present number of the Journal. It may be well to state, however, that the publication of a special "Students' Number" does not imply that students are or will be neglected at other times. Every issue of the Journal is educational in its tendencies; "Notes and Queries," "Dispensing Memoranda," and "The Month" being particularly so, and special assistance will always be freely given when asked for. At the same time, it may be suggested that students will best add to their stock of knowledge, and increase their ability to deal with difficulties, if they make a rule never to ask for assistance in their studies until they have exhausted every available means of ascertaining the facts required for themselves.

It should be needless to state that it is always desirable, if possible, that students should have the guidance of properly qualified teachers in their studies, and this applies to elementary no less than to more advanced work. Details are given in the Journal (see p. 215) regarding educational institutions throughout the country where suitable elementary instruction in scientific subjects may be obtained by pharmaceutical students, and at many other centres which are not specified the desired purpose is doubtless served equally well. No reasonable excuse, therefore, on the score of lack of opportunity in this direction is available to the majority of British students, and with a reasonable amount of diligence they should, as suggested last week, be in great measure prepared to pass the qualifying examination within a limited period of the expiration of their period of pupilage. Before proceeding to examination, however, it is always desirable that a special college course should be passed through. No attempt has been made here to deal with the institutions where such special courses are arranged, except in so far as their syllabuses include classes to which elementary students are admitted. In the course of time it will doubtless become not only desirable, but absolutely necessary, that a definite curriculum at a school of pharmacy should precede the qualifying examination. For the present, however, it will suffice to reiterate that the main point to bear in mind is that examinations should always occupy a subordinate place in any scheme of education, and preparation for them be regarded as something to be undertaken only by the way, for the worst and most unsatisfactory form of all study is that which has examinations for its sole end and aim.
THE LIQUEFACTION OF HYDROGEN.

In the Journal for January 12, 1878, a paper was published which had been communicated to the Paris Academy of Sciences, and in which M. Raoul Pictet described experiments performed by himself and M. Callier on the liquefaction of gases. Working with hydrogen, Callier observed what he described as an excessively fine and subtle fog suspended through the tube used in the experiment, and this he regarded as an indication of the liquefaction of the gas. Later, Pictet communicated to M. Dumas the information that he had succeeded in solidifying hydrogen, which was stated to have escaped from the apparatus employed in the form of a steel-blue liquid jet, and fallen in a hail of solid particles. These announcements have been accepted as statements of fact by the compilers of most modern textbooks on chemistry, but it was pointed out in the Journal at the time (vol. xxxvii., p. 552) that it was obvious the work was not yet done, and subsequent experience has fully confirmed this view.

In an article in the Times of September 1, it is shown that the possibility of liquefying a gas depends upon reducing the temperature of its critical point, no amount of pressure sufficing for the purpose unless this condition be fulfilled. Now, hydrogen has a critical point of about -240°, and the best means so far at command—liquid air or nitrogen—only admits of a temperature some forty degrees above this point being attained. It will be necessary, therefore, to find some new substance—such as may possibly be obtained by liquefying a mixture of hydrogen with 10 per cent. of nitrogen—having a critical point of -200°, i.e., some fifty degrees lower than nitrogen itself.

Assuming that such a liquid were available, its expansion into air would produce a much lower temperature than anything that has yet been recorded. This is proved by the fact that, in Professor Dewar’s hands, “such a mixed gas gives, under these conditions, a paste or jelly of solid nitrogen, evidently giving off hydrogen, because the gas coming off burns fiercely. Even when hydrogen containing only some 2 to 5 per cent. of air is similarly treated, the result is a white solid material (solid air) along with a clear liquid of low density, which is so exceedingly volatile that no known device for collecting it has been successful.

. . . . Knowing the difficulties from having to deal in the liquid state with the accumulated small impurities in such large amounts of gas, Professor Dewar will not declare that he has had pure liquid hydrogen in one of his vacuum vessels, although what this liquid can be except hydrogen it is impossible to say. The future progress of these costly and difficult experiments must depend very much upon questions of outlay, and it is to be hoped that the public will not assume that the endowment so handsomely given to the Royal Institution by Mr. Ludwig Mond (see p. 4) for the maintenance of a public laboratory of research, to be called the Davy-Faraday Laboratory, can be used for the prosecution of such investigations."

HERMANN LUDWIG FERDINAND HELMHOLTZ.

On Saturday last Germany lost one of her leading scientists, in the person of Professor von Helmholtz, whose death occurred at Charlottenburg as the result of an attack of apoplexy. Born August 31, 1821, at Potsdam, his father was a professor in the Gymnasium, while his mother was an Englishwoman. Helmholtz commenced his career as an army surgeon, and prosecuted his studies under considerable difficulties, but in 1848 he was appointed assistant in the Anatomical Museum of Berlin, and the following year he became Professor of Physiology at Königsberg. In 1858 he removed to Bonn, where he occupied the chair of Anatomy and Physiology, and three years later he was promoted to a similar position in the University of Heidelberg. Finally, in 1871 he was appointed Professor of Natural Philosophy in the University of Berlin, and the post he occupied until his death. He was the inventor of the ophthalmoscope, and was remarkable for his versatility and extraordinary fertility in scientific subjects. Equally at home in mathematics, mechanics, physics, chemistry, and physiology, he is credited in the catalogue of the Royal Society with over a hundred papers of the highest importance. The books by which he is best known are the volumes containing his popular lectures on scientific subjects, but his work on the “Conservation of Energy” is regarded as a classic, and equal importance are those on “Physiological Optics” and the “Sensations of Tone.” The Copley medal of the Royal Society was awarded him in 1873, and ten years later he was ennobled by the German Emperor.

JOSEPH PARSONS COOKE.

The death of Helmholtz in the Old World was shortly preceded by that of as well known a scientist in the New. Professor Cooke died at Boston, Mass., on Tuesday, the 4th inst. He had been connected with Harvard University for more than forty-four years, having been appointed Professor of Chemistry and Mineralogy there in 1850. He is said to have been the first in America to introduce laboratory instruction into the upper graduate course, and as director of the chemical laboratory at Harvard he has published several important works, including “Chemical Physical Researches” and “The New Chemistry.” In 1872 he was elected an honorary fellow of the Chemical Society, and in 1882 the degree of LL.D. was bestowed upon him by Cambridge Universi
SCIENCE PROGRESS.

The first article in the September number of Science Progress is one on "Snake Poison," by Professor W. Halliburton, F.R.S. A complete investigation into the subject of snake poison, it is pointed out, must attempt to answer three questions—What is the poison? what is its physiological action; and how can one best prevent or counteract this action?—but the majority of previous observers have begun at the wrong end, three-fourths of the references consulted treating exclusively of the third question. The work of recent observers is briefly summarised, and it is shown that their researches open up fresh questions to wide and important general subjects, such as blood coagulation and the poisonous nature of certain poisons. Mr. A. C. Steward, M.A., writes on "Algae as Rock-building Organisms"; Dr. Buckmaster contributes an interesting account of "The Biological Characters of Bacillus Typhosus (Eberth) and Bacterium Coli Commune (Escherich);" Mr. George Murray treats of "Fossil Algae"; Mr. Alfred Harker, M.A., of "Ancient Volcanic Rocks;" and Mr. E. H. Griffiths, M.A., of "The Determination of Temperature." In an appendix is given an "Index of theear of titles of chemical papers appearing in July, 1894."

PHARMACEUTICAL EDUCATION IN BIRMINGHAM.

At the opening of the classes in connection with the Birmingham Municipal Technical School, on Wednesday, September 5, the chairman of the committee, Mr. Councillor Martineau, pointed out that the classes in chemistry for pharmaceutical students, which commenced that day, represented only a preliminary step, and that the committee hoped it supported by those engaged in pharmacy to extend the teaching to other subjects. Mr. Coune and Mr. Beeley afterwards referred to the advantages which were offered by the school to apprentices and students, and said how important a training in chemistry was to the profession. Mr. R. D. Gibbs, resident of the Midland Pharmaceutical Association, also spoke of the necessity of increased scientific education, and referred to the fact that many students who presented themselves for examination were very ill prepared, owing to the lack of suitable training during apprenticeship.

CHEMISTS AND THE SELL OF POISONS.

Another instance of the indifference displayed by chemists towards the promotion of their material interests is afforded by a case reported in the Manchester Courier of the 12th inst. The matter is there represented, at the Over Session, Thomas Pickering, chemist and grocer, Winsford, was summoned for having, on 16th, sold to Jane Finney, a young woman, a bottle of vermin killer, containing strychnine, which she daily regurgitated, as required by Pharmacy Act. It was stated that Finney poisoned the poison, and died the same evening. Deprant, who, of course, expressed deep regret, paid 20s. and costs.

COMMISSION OF THE PEACE.

It is informed that the name of Mr. R. Wynne, chemist, Local Secretary for Dolgelly, has been placed on the Commission of the Peace for the county of Merioneth.

PHARMACY IN DEVONSHIRE.

In the Western Morning News of Tuesday there is an appreciative reference to the outcome of efforts recently made in the Plymouth district to advance the interests of pharmacy by such means as lie in the power of a local association. It will be remembered that the association was successful in obtaining a grant from the Pharmaceutical Society for the purpose of obtaining a materia medica cabinet. A sum of money from the funds of the association was added to this, and as a result about three hundred excellent specimens of organic and inorganic materia medica are now arranged in a case at the room of the association. There is also a small library of chemical and botanical books, and the visitors' book is said to show that the students are using the cabinet, etc., to the fullest extent. At a special meeting held within the past week it was decided to change the name of the association to the Plymouth, Devonport, Stonehouse, and District Chemists' Association. Under the care of the first president (Mr. J. G. Netting, Plymouth), Mr. J. Cocks, Stonehouse (hon. sec.), and many other chemists, the association has obtained a firm footing, and has now nearly one hundred members, consisting of qualified chemists, and assistants and apprentices connected with pharmacy.

ENGLISH MEDICINES IN ITALY.

A new regulation respecting imported medicines is referred to in a recently published report by the British Consul at Genoa, who observes that "hitherto there has been a considerable demand for English patent and other medicines, a variety of which have been kept in stock by the leading chemists, but I am informed that by a recent regulation, all compounded medicines sold in Italy must bear outside the package a recipe showing the ingredients of which they are composed."

APPOINTMENT AS BOROUGH ANALYST.

At a meeting of the Luton Town Council held on Tuesday, September 4, the Sanitary Committee recommended that Mr. Arthur Edward Erins, pharmaceutical chemist, of St. Albans, be appointed public analyst. The adoption of the report was agreed to unanimously, and the resolution ordered to be sent to the Local Government Board.

CONGRESS AT VIENNA.

An international congress of chemistry and microscopy will be held at Vienna during the last week in September. The president of the committee of arrangements is Hofrath Dr. E. Ludwig, and the secretary, of whom particulars may be obtained, is Dr. Hans Heger, I, Kolowrat, Pestalozziasse, 6, Vienna.

EXEMPTION FROM JURY SERVICE.

The lists of persons liable to serve as jurors for the current year are now being exhibited on the doors of all churches and chapels, where they are open to inspection. Pharmaceutical chemists whose names are included in the lists must, if they desire exemption, give notice to that effect to the local overseers during September. Otherwise they will be liable to serve on juries.

EDINBURGH PHARMACY ATHLETIC CLUB.

We are asked to announce that the Annual Picnic of this Club will take place on Monday, September 17, to Crichton Castle. The brakes will leave St. Andrew Square at 9.30 a.m.
International Congress of Hygiene and Demography.

MEETING AT BUDAPEST.

The eighth International Congress of Hygiene and Demography was formally opened at Budapest on September 2, by the Archduke Carl Ludwig, in the name of the Emperor of Austria. The Archduke was supported by Dr. Wekerle, the Hungarian Premier, and other members of the Ministry, as well as by the Burgomaster of Budapest and other dignitaries. After an opening address by M. Hieronymi, Minister of the Interior, the Archduke declared the Congress open. He referred to the proof afforded by such assemblages of the great importance now attached to hygienic questions, and concluded with welcoming the foreign delegates. The welcome was duly acknowledged by the latter, Professor Corfield reporting the proceedings. At the close of the formal proceedings, a Court reception was held by the Archduke, at the Castle, in the evening.

The practical work of the Congress commenced on Monday, September 3, when nineteen sections assembled, and some 2000 members were present. Amongst the papers read was one by Princess Christian on the progress made in the care of the sick, and the extension of sanitary and hygienic knowledge in Great Britain. A report of an inquiry into the physical and mental condition of school children was then received from the British Committee appointed in 1891, of which Sir Douglas Galton was chairman. Miss Florence Nightingale contributed a paper on "Village Sanitation in India," and Sir William Moore on "Tropical Dietetics." Several papers on sewage ventilation, water filtration, etc., were also contributed, while Professor Corfield dealt with "The Protection of Dwellings against Sewer Gas," and Dr. Worthington considered the systems of dwellings for small wage-earners. Mr. W. M. Aecworth read a paper on "The Methods adopted in London for Dealing with Smallpox Outbreaks," and the question of epidemics was treated generally in one of the sections. An exhibition was opened during the week, and the Royal Photographic Society of London had a special meeting held during the afternoon in the State Hall of the Royal Academy of Science, when Professor Huyghe delivered an oration in memory of Ignatz Semmelweis; and in the evening a Court reception was held in the Royal Palace. Special performances were also given at the opera and most of the theatres.

On Tuesday, reports from various centres upon diphtheria and its treatment were received and discussed. Professor Löffler pleaded for systematic bacteriological examination in all cases of diphtheria, and said no doubt now existed as to the identity of the diphtheria bacillus. It could be present in the nose or larynx without producing symptoms of the disease, and when protected from light could survive in organic matter outside the human body for several months. Dark, damp, and dirty dwellings, therefore, favoured the preservation of the organism, and helped to spread the disease. Various measures and dwellings humble of light and air, careful cleansing of the mouth and nose, and gorging of the throat with solution of salt and carbonate of soda, were recommended as prophylactic measures by the German committee. The report of the American committee was presented by Dr. Billings, and the Irish report by Dr. Edward Seaton, Lecturer on Public Health at St. Thomas's Hospital. A French report was also presented. Several papers on leprosy were read in the oriental section, together with others on tropical affections of the liver, severe in India, the recent outbreak of bubonic plague in Hongkong, and the Ramadan. The subject of cholera was introduced on Monday was confined in certain instances, and in the afternoon the delegate witnessed the athletic sports organised by the Lusitana Athletic Club for prizes offered by the Congress. The chief subject considered on Wednesday was cholera, its bacteriology, the conditions under which it spread, and the measures necessary to combat it. Twenty-six papers on the subject were on the agenda, by Dr. Brouardel, Professor Gruber, M. Metschnikoff, and others. M. Metschnikoff stated that the cholera microbe might be present in water long after an epidemic had ceased, and be capable of producing a fresh outbreak. At the same time its presence in the water did not necessarily involve an epidemic. Reports on diphtheria were also received, and papers were read on the methods of classifying school children as to their bodily and mental conditions, and the provision of mortuaries and oorooms' courts.

This Monday was a general holiday for the different sections, being devoted to excursions to various places of interest, and on Friday the discussion on cholera was resumed. A controversy on the construction of workmen's dwellings occupied the combined ninth and tenth sections, and a discussion on the optimum conditions for the building of housing, and the geographical distribution of diseases, and the climatology of Africa. Professor Cayley stated that poorly housed natives in malarial districts in India were enabled to go through their daily work better by the aid of opium. Other papers dealt with the prevalence of scar fever in the tropics, the physical and climatic conditions of India, and contagious diseases among European soldiers in India, while tuberculosis constituted the chief topic for discussion by the bacteriological section. Dr. Reibmayr, of Ischil, stated that the more a population suffered from tuberculosis the less it was liable to outside contagion, and the general immunity from contagion could only be attained when all nations were equally tainted with tuberculosis poison. In the evening a reception was held by Dr. Wekerle, the Hungarian Premier.

On Saturday, a paper on cholera was read by Dr. Ernest Hart, in which he reiterated the views that has been expressed by the Royal Photographic Society as determining the germ theory and treating of the several malignancies of malaria were afterwards considered. In the afternoon a plenary sitting of the Congress was held in the Town Hall, to receive and consider the resolutions formulated by the sections. Some confusion arose respecting to these owing to some of the questions being neither printed nor translated, whilst one attempted to explain or defend others. Dr. Bills protested against the wholesale adoption of imperfectly understood and unexplained resolutions, and urged that an international Congress should only pass resolutions which were universally agreed upon. The voting proceeded, however, as usual, and the names of the members whose names were inscribed on the roll of the Congress a very small proportion was present, as were twenty remaining towards the close of the proceedings. A resolution in favour of entrusting pharmacists who had acquired the necessary qualifications in the preparation of medicines in the case of workmen engaged in hazardous industries, in third in favour of the extension of the national curriculum of science and in hygiene teaching to schools of all grades.
applying a committee to consider the best conditions and methods of constructing workmen’s dwellings, and one in favour of the reduction of light beer and of increased taxation on spirits. In the afternoon many members of the Congress witnessed a grand parade and drill of the city and provincial fire brigades in the courtyard of the artillery barracks. Others attended the races organized by the Hungarian Cyclist Society in exemplification of the hygienic advantages of outdoor physical exercise. In the evening the delegates were entertained by the Municipality of Budapest in the Great Industrial Hall.

The Congress was formally brought to a close at a general meeting in the municipal redoute on Sunday, M. Hieronymi, Hungarian Minister of the Interior, presided, and all the official representatives of foreign governments were on the platform. The usual official reports regarding the work of the Congress were presented, and the permanent committee was re-appointed, the name of Dr. Foore, of London, being added, in recognition of his excellent services. At the London Congress of 1891, it was resolved to hold the next Congress at Madrid. M. Ginens, in the name of the Spanish government, expressed his pleasure at this decision, and assured the Congress of a warm welcome. Professor Cordfield read the following letter from the secretary of the Prince of Wales, explaining that it should have been read at the opening of the meeting, but had not been received in time:

“Dear Sir Douglas Galton, I have submitted your letter and enclosures to the Prince of Wales, His Royal Highness would be glad if, in your reply at the Congress, you would allude to the interest which he takes in hygiene and demography, and to the fact that he was president of a similar Congress in 1891. Perhaps you would also express his gratification at hearing that the Emperor has allowed his name to be connected with a gathering called together to discuss such important questions. Yours very truly,

“FRANCIS ENOLLY”.

The official delegates of other countries having returned thanks for the hospitality extended to them during their visit to Budapest, M. Hieronymi delivered the closing address, referring to the great importance of the discussions which had taken place, especially the question of the necessity of a proper classification of poisons.

The Congress then dispersed, large parties leaving in the course of the day on excursions to Belgrade, Constantinople, and other places.

**Provincial Transactions.**

**Plymouth District Chemists’ Association.**

The Plymouth, Devonport, Stonehouse, and District Chemists’ Association held a special meeting at the Forester’s Hall, Union Street, Plymouth, on September 5. Among the members present were Mr. J. W. Deacon, President (in the chair); R. H. Randell, C.C., and F. W. Hunt, Vice-Presidents; F. Mattiand, W. Condy Uren, A. D. Breeze, J. Barne, Barber, R. F. Roper, J. H. Bailey, Hon. Treasurer, and James Cocks, Hon. Secretary. Several motions were brought forward, in connection with the rules and bye-laws, at the annual meeting, to be held on October 10 next, and the first annual dinner on that day; also for the election of officers for the ensuing year. A full discussion on the motions brought forward by Messrs. J. Cocks, J. G. Notting, R. F. Roper, R. H. Randell, and W. Condy Uren, was taken part in by the members present. The new committee, consisting of Mr. Cocks, Mr. T. H. Deacon, Mr. J. F. Roper, Mr. J. H. Randell, and Mr. W. Condy Uren, was appointed to act in the absence of the members present. The new committee was warmly received in the room, and was greatly admired, and gave general satisfaction. A vote of thanks to the chairman, proposed by Mr. R. F. Roper, and seconded by Mr. F. W. Hunt, was unanimously carried.

**Sunderland Chemists’ Association.**

A social evening of the above Association was held at the Fawcett Street Cafe on Thursday, September 6. The following members and friends had gathered together at the appointed time:—Messrs. J. H. Randell, President; Jno. Mitchell, Vice-President; W. W. Leadbitter, Treasurer; R. H. Bell, Secretary; C. Ranken, T. Walton, M. J. Dodd, C. Hodgson, A. D. Pike, J. R. Askew, A. B. Porter, H. B. Watkin, A. Goldightly, T. B. Harrison, R. Robinson, E. R. Cherrett, J. H. Bell, A. O. Bell and J. W. Moore.

The President opened the proceedings by presenting Mr. R. Robinson, on behalf of the Association, with a beautiful pair of gold spectacles, as a token of esteem and recognition of his services as Treasurer for the past twenty-four years. Mr. Robinson feelingly replied, and reviewed the work and the ups and downs, etc., the Association had gone through since he had first joined it.

The remainder of the evening was occupied by a description of a trip to the Chicago Exhibition, Messrs. Ranken and Walton officiating as the lantern after which music, etc., was indulged in. Votes of thanks to the President and those who had taken part in the entertainment were passed, and the company then dispersed.

**American Pharmaceutical Association.**

**Can a Minimum Standard of Pharmaceutical Education Be Adopted?**

By Oscar Oldberg, Ph.D.

More or less definite compulsory courses of pharmaceutical education are established in most of the civilized countries of the world. England and the United States are the notable exceptions. The chief reason why pharmaceutical education has not been made compulsory through the enactment of direct special laws in England and America is evidently to be found in the fact that in these two countries there is unlimited competition in the retail drug business, while in the other countries the competition is limited. Nevertheless, England and America have sought to accomplish at least something in the same direction by indirect legislation, declaring that every person who is granted a licence to practise pharmacy must first have completed a certain course of studies in a pharmaceutical school, the pharmacy laws of England and America simply require that the applicant for such licence shall pass an examination conducted by the official pharmaceutical examiners representing the State. But compulsory pharmaceutical college training has recently been established even in Ontario and Quebec, Canada, and in Victoria and Queensland, Australia, in which countries the retail drug business is carried on in the same way as in America. Therefore, it ought to be considered standard by American standards of pharmaceutical college training in this country too. This can, of course, be done only by legislation. That such legislation will surely be undertaken, sooner or later, we may know from the steady progress of pharmaceutical legislation in all lands. We can in hope for wise laws if the whole subject in all its bearings be carefully considered by competent, conservative, broad-minded men, uninfluenced by personal prejudices, and a definite plan agreed upon by them to serve as a basis for these laws. I, for one, feel hopeful that this can be accomplished.

Before any laws shall be enacted to establish compulsory pharmaceutical education, it would seem to

* Read at Asheville, North Carolina, on September 6.
be highly desirable that a body of thoroughly representative men should give this question their most deliberate and earnest consideration, and formulate an authoritative declaration as to what should constitute a minimum course of pharmaceutical education, or if these views should conclude that more than one class of pharmacists ought to be recognised, each with its own standard of minimum requirements as to education, then these respective standards should be formulated.

This body might consist of delegates or members elected by the American Pharmaceutical Association, the Boards of Pharmacy of the respective States, and the several pharmaceutical schools or colleges. Ample sufficient time should be taken to give due attention and thought to the question. If one year is not found sufficient, let two years be devoted to it.

It should be the duty of that body not to attempt simply to equalise or harmonise the different standards or courses now given in existing pharmaceutical schools and colleges, nor to effect any compromises between them. A body or commission constituted in any such manner as here suggested could have no pretence to represent the colleges, and its conclusions any more than this Association could establish uniformity in the methods and educational standards of the several colleges. On the contrary, the commission, should one be constituted, must, in order that its conclusions may command respect, avoid being unduly influenced by the methods or standards of any of the existing schools. It should, instead, think out and formulate, ab initio, such a plan and such standards as may seem to a majority of its members to be wise and practicable, and to best subserve the interests of the people, the medical profession, and true pharmacy, wholly regardless of the present or prospective practices, plans, or interests of any teaching pharmaceutical institution or institutions, and without any thought of trying to coerce any such institution into any degree of conformity to the conclusions which the commission may reach.

The conclusions formulated by the commission may not closely resemble the requirements or practice of any one of the existing pharmaceutical schools. Indeed, the differences between different institutions are so considerable that the independent views of the commission would probably not conform to those of any one of them. But if the conclusions of such a commission would uphold the true interests and dignity of pharmacy, if they have the stamp of wisdom, justice, and independent thought, and if they be practical, their moral weight will accomplish more for the recognition, spread, and further advancement of sound pharmaceutical education than any compromise or rivalry between the colleges, or any vote or resolution passed by any association.

No standard of pharmaceutical education can be of any value unless sufficiently well defined to ensure a reasonably close approach to uniformity of interpretation. Nevertheless, any unnecessary details should be avoided in its formulation.

Upon the invitation of the officers of this Section of the American Pharmaceutical Association I submit herewith some facts and questions which seem to me to require very careful consideration in this connection:

1. What should be the minimum of preliminary education required of all who shall enter upon their apprenticeship in pharmacy, or who shall be admitted to a college or school of pharmacy?

2. Should there be but one class of college trained pharmacists, and if so, what should be the minimum of special education required? If more than one class of college-educated pharmacists be deemed necessary, what should be the minimum course of special education of each class?

3. Should not the minimum standards recommended be such as can be made compulsory by law in the near future?

4. What courses of study ought to be included in the obligatory curriculum, and how wide should be the field of study in each distinct subject?

The answer to this question must, of course, depend upon:—(a) the number of months devoted to the entire course of education; (b) the number of hours' instruction and textbook study during the same; (c) the preparatory education demanded of the students; (d) whether the course is intended to be partially or eventually made obligatory upon every pharmacist, or only upon those who voluntarily attend colleges of pharmacy; (e) whether the student devotes their whole time to their school work, or divide time between the college and the shop; and (f) what is practicable in view of the actual condition of the practice of pharmacy, and those engaged in it.

5. How many months or weeks should be devoted to the entire course of special college education?

The answer to this question must necessarily be governed by the time in which the student can be trained under such circumstances whether or not the student gives his whole time and attention to his studies, and is well occupied; and if the student's time is divided between his studies and everyday shop employment, then the question must be: what proportion of his time is really devoted to his school work?

A "three years' course" with but five months' work each year would be a very different thing from a "three years' course" with nine months' work each year; six months' work with the student's entire time and attention devoted to his studies is a very different thing from six months divided between study and wage-earning; ten hours' instruction weekly for a month is not to be compared to thirty hours' instruction weekly of the same kind during the same length of time; and a course consisting of lectures only is entirely different from a course including also laboratory practice.

It is, therefore, self-evident that the value of a course of education is not to be measured by the number of calendar months through which it extends; but that many other and much more important conditions must be considered in connection with it.

6. Should not the students be required to devote the whole time and attention to their studies, to the exclusion of drug store employment or any other outside occupation during the entire college course? If not, how much longer should the college course be continued in order to offset the time lost by simultaneous wage-working?

7. What should be the minimum amount of obligatory school attendance weekly during the course?

In the pharmaceutical schools or colleges the actual practice varies considerably; the instruction occupies 6, 10, 12, 15, 19, 30, and 40 hours weekly.

8. What should be the minimum amount of obligatory laboratory practice in chemistry, pharmacy, and pharmacognosy, respectively?

In actual practice the total obligatory laboratory work varies in different colleges from zero to over twenty hours weekly.

Can any valuable laboratory course in chemistry be accomplished in less than 250 actual working hours? And would it be too much to expect 300 hours actual laboratory practice in chemistry, and the same number of hours in pharmacy as the minimum?

And, finally, if a "standard" is adopted, should it be the most complete and thorough course of pharmaceutical education practicable, without regard to time and expense, or should it be the best course the average
The pharmacist might be able and willing to accomplish.

The pharmacy laws of Ontario, Quebec, Victoria, and Queensland are, perhaps, not explicit enough, but the colleges of pharmacy in those provinces have courses occupying six or more months. The School of Pharmacy of the Pharmaceutical Society of Great Britain at London gives a course of ten months, with the student's whole time devoted to his school work. Can a longer course be made a national minimum in America? If so, let us adopt a longer one.

In actual practice the American pharmaceutical schools or colleges give courses ranging from forty weeks to four years, if we are to compare them by the calendar time occupied. We have courses of 40, 42, 44, 46, 50, 52, 60, 76, 114, and 182 weeks not time respectively. At least seven pharmaceutical schools now offer courses occupying two years, with nine months' full work in each year.

It is greatly flattering that ambitious and eager students of pharmacy in our country can now take solid thorough courses extending over two, or even three or four years of full time, while the schools are of great value and importance, and must exert considerable influence upon the further improvement and spread of pharmaceutical education, it is certainly equally true that those colleges of pharmacy which are striving to give as extended a course as a considerable number of students can be induced to take under existing conditions, are entitled to equal respect and support, and are performing an even more important use. Who shall answer which is the more important, the school for the thousands, the school for the hundreds, or the school for the tens?

Although there are at least 100,000 persons employed in the retail drug business in our country, and more than one-half of these are compounding medicines on physicians' prescriptions, probably only about 10,000 of them are graduates in pharmacy, less than 3700 annually attend any pharmaceutical school, less than 900 annually finish their college courses, less than 300 annually attend colleges in which the minimum of time required for the completion of the course is at least two terms of nine months each, and less than 100 of these have got beyond their first nine months' work. Nearly three-fourths of all the pharmaceutical students in the United States drop out after the first year or two. In other words, many devote only from twenty to thirty weeks of their life-time to the special studies intended to prepare them for their life. Nearly nine-tenths of the persons who become registered pharmacists and assistant pharmacists never attend any college of pharmacy.

We may well ask, then, how after a greater number of the persons employed in pharmaceutical work in our country be induced to attend the colleges of pharmacy, and how shall all who hereafter seek registration and licence to conduct drug stores in which all kinds of technical pharmaceutical work is done, be induced to acquire the special education requisite for their vocation, or for the accomplishment of these ends I do not believe that any substantial progress can be made by attempting to establish but one standard course of pharmaceutical education, or by a rivalry among the schools to give the longest course. If the apparent tendency continues, we shall have, perhaps, colleges of pharmacy occupying five or six years, before long. What we should try to do, it seems to me, is to gradually elevate the whole body of pharmaceutical workers to a somewhat higher plane, educationally, than they now occupy, and a portion of them still higher than the rest. In other words, let the course of the study take care of itself. Let us go down a little nearer to the level of the average education of the pharmacists of the day and bring them up to as high a standard of special education as seems practicable, and let us be careful not to attempt to do at once that which it will certainly require many more years to accomplish.

Let us not make the grave mistake of adopting a minimum standard of special college training in pharmacy so high as to be beyond the reach of the majority of the rising generation of clerks and apprentices. Instead, let there be two standards.

It seems to me that each college of pharmacy might give two different degrees—perhaps, one full year's work substantially as in the School of Pharmacy of the Pharmaceutical Society of Great Britain, and another representing an additional year's full work.

It is useless to ignore the fact that a large majority of all students are greatly influenced by their ambition to secure a degree and a diploma as evidence of their work. Is there any valid objection to the adoption and general recognition of two different courses and degrees—one course intended for the great majority of students and to be eventually made the obligatory minimum course for assistant pharmacists, and a higher or longer course with a higher degree intended to be eventually made obligatory for managers of pharmacies of the higher class?

If an able commission should formulate practicable minimum standards I venture to predict that every school of pharmacy in the country would at once and cheerfully do more than these standards require.

No school need feel called upon to give more than one fixed course or degree, be it the lower or the higher of the two. Any school would still feel free to make its courses as much higher than the minimum standards as it may deem best; and there would be nothing to hinder any school from adopting a course two or three or ten times as exacting as the highest standard recommended by the commission. There would always be plenty of room at the top; what we most need is a limit at the bottom.

The successful issue of such a movement as this would bring with it another result. It would necessarily help to minimise the jealousies and rivalries which exist between the several institutions—"a consumption devoutly to be wished."

Parliamentary and Law Proceedings.

POISONING CASES AND INQUESTS.

The Use of Infant's Powders.

At the Shoreditch Tabernacle, on September 29, Dr. Wynn Westcott, coroner for north-east London, held an inquiry into the circumstances attending the death of Agnes James, aged one year and eight months, the daughter of a postman. The mother deposed that on Friday last, as the child was feverish, she sent a little girl to "Dr. William Spooner" for a 14d. Steadman's poison powder. The girl returned with a pink powder and told witness that she had asked for a 14d. powder for a baby eighteen months old. The powder was given to the baby. About two hours later the child was seized with a convulsive fit. Dr. Irvine prescribed for it, but death ensued next morning. Minnie Hardy, the wife of a herbalist, of Hoxton Street, stated that she supplied the powder. The Coroner told her that, as there was a possibility of a criminal charge being preferred against her, it was his duty to caution her. She hesitated about giving evidence, so the testimony of Dr. Irvine was taken first. He stated that deodar's root was added to the calomel contained in the powder. A juror remarked that the instructions on the packet produced said that only half a packet was to be given to a child.
under three years of age. The mother had given the whole of the powder. Mrs. James explained that she could not read. Mrs. Hardy said that she felt in a very awkward position. The Coroner said that in the circumstances he should advise her to tell all she knew. She then stated that on Friday afternoon she was asked by a little girl for a "1/4 powder," and gave her one similar to that produced, labelled "Dr. Williams's Child's Blessing." There were full instructions on the packet, and the powders were made from a prescription of her father's. He had been dead several years. His name was Morgan Edward Williams, and he was a chemist. The Coroner remarked that Mr. Williams's name was still on the chemist's register, and that it ought to be removed. Harry Hardy, husband of the last witness, stated that he was not practising as a chemist. His premises were called "Williams's Drug Stores." He at first denied that the name "Dr. Williams" was on the premises at all, but he admitted at last that it did appear on the lamp outside the shop. Eventually the jury returned a verdict in accordance with the medical evidence, and recommended that in future such powders should not be sold to young children.—Times.

DEATH FROM AN OVERDOSE OF CHLORAL.

The Leeds City coroner (Mr. J. C. Malcolm) held an inquest at the Leeds Town Hall on September 4, on the body of Arthur Fryer, aged 52 years, commercial traveller, of Portinscale Lodge, Higher Broughton, who had died at the Albion Hotel, Briggate, Leeds. According to the evidence the deceased was found dead, and on the dressing-table was a bottle about half full of chloral. Death was due to a dose of that drug. Dr. Greville, a medical man resident at December, the deceased's house, who examined the post-mortem resident, said he was personally acquainted with that gentleman. He had known that he was a sufferer from dyspepsia and insomia, and hearing that he had become addicted to taking chloral, warned him against the habit. He was certainly of opinion that death was due to an accidental overdose. Deceased was a man of a most cheerful disposition, and was not likely to have committed suicide. A verdict of "Death from misadventure" was returned.—Yorkshire Evening Post.

DEATH FROM OVERDOSE OF OPIUM.

An inquest was held at Heathfield Hall, on Tuesday, August 28, by Mr. E. Bedford, touching the death of Mrs. Susan Glover, aged 62 years, widow of Mr. Robert R. Glover. The medical evidence was to the effect that death was probably caused by deceased having taken an overdose of opium, and the jury returned a verdict of "Death from misadventure."—Sussex News.

DEATH FROM OVERDOSE OF LAUDANUM.

On September 7 Mr. Hanly, inquest touching the death of Charles Garton, 48, labourer, of Castle Donington, who was found dead in bed the previous morning. Evidence was given to show that deceased had been in the habit of taking laudanum, and Dr. Fletcher said he was called to see deceased about 8.30 on Thursday morning, and found him dead in bed. He said he had apparently been taking it some hours previously. There were no marks of violence. He examined the pupils of the eyes and found them dilated. The face seemed to be drawn rather to the right side, and congested on the side. Witness had an idea that deceased suffered from dropsy. He found no evidence that deceased had had any idea that death was due to an overdose of laudanum. Three draughts would kill a man not in the habit of taking it. The jury returned a verdict that deceased died from the effects of an overdose of laudanum taken by himself with the intention of securing sleep and rest, and not with the intention of committing suicide.—Leicester Daily Post.

DEATH FROM OVERDOSE OF CHLORODYNE.

Mr. Bush held an inquest on Saturday, August 25, at 8, Clarence Square, Brighton, touching the death of Edward Croft Sykes, a retired surgeon, late of 4, Wellington Circus, Nottingham, who died early on the previous morning at 8, Clarence Square. The evidence went to show that the deceased, who was 64 years of age, and was staying with his sister in Clarence Square for the benefit of his health, had been in the habit of taking chlorodyne. Mr. F. Sloman, surgeon, was sent for on Wednesday and found him unconscious. He applied remedies, but deceased gradually sank, and died early on Friday morning. Mr. Sloman had made a post mortem examination, and considered that death was due to an overdose of chlorodyne. The jury returned as their verdict that the deceased died from the effects of an overdose of chlorodyne taken by misadventure.—Brighton Observer.

POISONING BY LAUDANUM.

A curious case of mixing laudanum with a baby's food came up at the Islington Coroner's Court on September 4. Amy Raymond, of Hemingford Road, Barnsbury, said that the deceased child had lately suffered from diphtheria and was very restless, depriving her of sleep at night. She had been in the habit of taking doses of laudanum herself, and on the Friday night, when baby was very cross and restless, she happened to have sixpennyworth of laudanum in a bottle. It occurred to her that a "few drops" in the baby's milk might have the effect of sending it to sleep. Hence she poured a "very little" of the laudanum into the jar containing the milk, and then divided the liquid into two lots. The first lot was used for the baby's bottle on Friday night. Notwithstanding the drug the child continued sleepless and restless during the night. The next morning, forgetting all about the tincture of opium, she administered the second lot of baby's food. Then the child became alarmingly ill and died on the Sunday.

The doctor's conviction was that the mother acted in ignorance and without any other design than to make the child sleep and do it good.

The jury, in returning a verdict of "Death from misadventure," blamed the mother of the child for her thoughtlessness and carelessness, the coroner remarking that it was not requisite to have a medical knowledge in order to realise that laudanum, dangerous to adults, must be infinitely more so to children.—Morning Leader.

Notes and Queries.

SOFTENING HARD EXTRACTS.

[768.] I have found that a mixture of glycerin and water in equal parts, such as is often kept on the dispensing counter for convenience, answers admirably for softening hard, watery extracts such as belladonna, previous to incorporating them with fats for suppositories or ointments. Glycerin alone, as your correspondent suggests, does not answer well, which is probably due to its hygroscopic nature as much as to its slippery character in the mortar or on the pill-slab. For resinous extracts such as cannabis indica, spirit would seem to be the natural thing to use for softening, and experience quite bears out that conclusion.

E. F. Young.
PHOSPHORUS PILLS.
[769.] Method No. 3 is one which makes good pills, and is easy to manipulate. Many dispensers pour a few drops of chloroform or spirit of chloroform upon the mass whilst making, to prevent oxidation.

E. F. YOUNG.

PREPARATION FOR CAVITIES IN THE FACE.
[772.] I have been requested by an ear and nose specialist to make up for him some neutral preparation that he can use as a basis for filling up cavities in the face. He desires something that will be capable of use with an obturating syringe, and yet solidify enough not to run out after insertion. Gelatin has been found unsuitable, and the best result has been obtained with a mixture of glycerin and starch. This does not quite answer the conditions, however. Briefly, what is required is a substance, waxy or otherwise, fluid enough at a bearable temperature to inject, yet that will form a soft mass at the temperature of the blood and could be washed out, when required, with warm water.

ARTHUR MCKELLAR.

DIGESTIBLE MILK.
[773.] The difficulty sometimes experienced by invalids in taking and assimilating milk is well-known, but is said to be surmounted by the following process—devised by Dr. Robert T. Eedes, of Boston—for making the fluid palatable and digestible. A pint of milk is gently warmed, and whilst it is constantly stirred twenty minutes of dilute hydrochloric acid is dropped into it very slowly. If the milk is stirred until cool, a very fine flocculent coagulum is produced, which floats in the whey and is easily accessible to the digestive secretions, while the whole fluid has lost to a great extent the taste which renders it unpalatable. Special advantages of the method are that the casein is retained and used, and the milk is not bitter as when pancreasised (New York Medical Record).

Dispensing Memoranda.

[652.] Herewith I send you three prescriptions which may be of interest. The first is a German prescription, and as the name for cold cream (unguenteni, vide U.S. Dispensatory) was new to me, it may be of interest to others.

A. Hydrag. oxyd. rubr. 0:15
   Ungt. lenient 2:0
   Lanolin 8:0

The ointment for the eyelids.

The second, prepared in a porcelain basin in the order given, with the aid of a pestle, gives a good result, but if the stirring be overdone, the water begins to separate out.

A. Plumbi. oxid. 2v.
   Ac. acetic. dil. 20x.
   Coque simul. ad. 3xii.

Add Lanolin
   Oil. olives
   Ammon. sulph. ichthyol 2v.

In the third, if the styrax be first rubbed down with spirit (vide ung. styracis, Martindale), there is no difficulty, but I wondered if the physician had in view the formation of sulphurated lime. This I should not expect on heating, while carbonic acid itself tends to decompose such sulphides with formation of carbonate.

B. Styrax prep 3a.
   Ungt. sulph. 1l.
   Crete prep 2l.
   Vaselin 3l.

JAMES GRIEVE.

Obituary.

EDWARD HORNER.

The death of Mr. Edward Horner, formerly of the firm of Horner and Son, occurred September 1, at Crayford, Kent. Mr. Horner, who was in his eighty-first year, was one of the founders of the Pharmaceutical Society, and as such responded to a toast at the Jubilee dinner of the Society in 1891. He was also a Justice of the Peace and a member of the Salters' Company.

Notice has also been received of the death of the following:

On August 14, James Dunsmore, Chemist and Druggist, Garliestown. (Aged 82.)
On September 6, Emanuel Hutton, Chemist and Druggist, Leeds. (Aged 66.)
On September 6, Atkinson Pickering, Pharmaceutical Chemist, Hull. (Aged 74.)

Patent Office Business.

APPLICATIONS FOR PATENTS.
No. 15,535.—August 15, 1894.—John Wallace, 34, Highfield Road, Rathgar, Dublin, for a cure for influenza. (No. 16,771.—September 1, 1894.—Jane Darby Lucy, 32, Queen's Terrace, St. John's Wood Road, N.W., for a new or improved medicine for indigestion.

APPLICATIONS ABANDONED BY APPLICANTS.
No. 17,976.—September 25, 1888.—Charles George Hawkes, 63, King's Cross Road, for a nailing or embrocation.
No. 18,177.—September 28, 1889.—George Thomas Hall, 32, Arthur Street, Plumstead, for an improved skin specific.

Correspondence.

THE NOMENCLATURE OF OFFICIAL REMEDIES.

Sir,—It was with great pleasure that I listened to the able and scholarly paper read by Mr. Joseph Ince within the classic walls of the grand old College of Belfast. In the preparation of the last edition of the British Pharmacopoeia the various committees did good service in altering several faulty formulae, and also re-naming substances according to the latest scientific theories advanced. Surely the time has now arrived when any semblance of "dog-Latin" in our national pharmacopoeia should be swept away, and that the Latin contained in it shall be as pure as that taught in the ancient University of Oxford. I well know that in this age of new synthetic remedies the discoverer has to invent a " coined" word if he wishes to register and patent it, e.g., antiyprine, vaselin, and lanolin. I urge strongly, however, that the example inaugurated in the latest Addendum of substituting scientific terms, as phenacetin, paraffinum molle, etc., be adhered to, and also that the ordinary rules of declension be followed. I am convinced that this is the earnest wish of medical men, who frequently follow the terminology suggested by Mr. Ince. I certainly think that the terms alumin, pyroxylin, emulsion mentholis, haustus sulphonalis, tinctura kinonis, ipumus cuseonis,
lignon gatta-percha, and syrups chlorals are more correct than those in vogue, and hope that they will be adopted in the next issue. Of course, if any words of Greek origin are introduced, let them also follow the usual conventions of that language, as the old-fashioned καπνολας—καπνολωσ.

Rensgate.

W. F. GADD.

THE REVISION OF THE BRITISH PHARMACOPEIA.

Sir,—A young gentleman from Clapham Park writes somewhat warmly in your last issue concerning my ideas of ointment making, and it is mainly to save him from some needless trouble that I am writing this in reply. I am referred to a paper on the subject to be found in the Journal for April 14 last; that paper I did read at the time; indeed, I have made it a part of my business to read my Journal for upwards of thirty years—but having reason to disagree with almost every one of the statements therein, and as any reply from me would have been but a repetition of what I had already advanced in a paper read before the Western Chemists' Association, of London, and published in the Journal a year or two previously, I thought it best to take no further notice of it. With reference to boric ointment, let the following anecdote suffice:—When the article was first introduced—the very week we got it into our new paper—the firm brought us a prescription to be dispensed, for two ounces of this same ointment. Having none ready, we asked for an hour for its preparation, and at once set to work. The first stage was to heat the saucepan of boiling water, a sieved made of a piece of muslin stretched across a two-ounce willow box with the bottom cut, kept in position with the rim of the lid, and clamped with the other lid, and a small gas stove, comprised our set of apparatus. One of us sifted in the powder whilst another stirred, and stirred till cold, with no signs of aeration whatever. The result was emulsion, which cost us all round; for the prescription having been taken elsewhere, and the charge of Rs. 1 6s., we gained a little éclat by the transaction, and a good customer into the bargain. Since then we have prepared the article on a somewhat larger scale with uniform success. Sometimes we have been compelled to purchase it ready-made, then it has never been twice alike. Why? I wonder. Many may charge me with being most uncharitable, but I cannot forget the conviction that it is a case of trade conscience versus quality. As a rule, what is pure lard? why adeps preparatus, P.B., which I reckon to be the most valuable product of pig-life.

West Marylebone.

J. C. HIELSP.

Paraffinum.—I have previously advocated the introduction of a medium paraffin.—Take of soft paraffin, 6 pounds; hard paraffin, 1 pound; melt together. This answer admirably for nearly all ointments, and is far superior to applying to the eye than the present formula for ung. ac. boric. Ung. hyd. nit. dil. should be made thus:—Take of nitrate of mercury ointment, 1 oz.; white soft paraffin, 2 ozs. Mix. I cannot agree with Mr. Hielsp that it does not perfectly purify lard will keep much better and longer than paraffinum molle.

Tinctures.—Having recently published my method of making tinctures, which does not vary much from the B.P., the B.P. itself may say more, but from what I have written is late by Mr. Parker and others. I tried forcing with water, but gave it up four or five years ago, except for tr. singib. fort.; for if the water commences to pass during the night, it often goes through rapidly, and instead of finding an ounce or two of tincture in the morning, perhaps a pint of mixture would be there. Possibly the added water could be regulated as to quantity, but not easily in the half-gallon conical percolator.

Dr. Sew. An "inert preparation of an active drug." (B. S. Proctor.)

Ung. Acid. Carboniae.—I agree with Mr. Hielsp that the acid "cozes out," and that the paraffin basis is unsuited to this ointment.

Ung. Gallis cum Opio.—Here I would give the formula in full, thinking it advantageous to rub the powders well together first. The following quantities are practically the B.P. proportions:—Take of opium in fine powder, 227 grains; galls in fine powder, 480 grains; benzoined lard, six ounces. Mix thoroughly.

Ung. Hyd. Oz. Rub.—The paraffin medium makes a fine ointment of fair consistency and non-changeable. The landscape oiled should be ordered.

Ung. Hyd. Ammon.—I would continue the present form. It has a very different appearance when made with the paraffin basis.

Resin.—I have not tried the powdered resin, as recently suggested by Mr. Hielsp, but the powdered resin of trade commonly contains a small proportion of farinaceous matter, and probably pulverized resin var. would only be obtained by specially ordering. I use the resin in small pieces, melt in an iron evaporating dish over a naked flame, and quickly add the wax, etc., then strain and stir as directed.

Northampton.

J. CLOVER.

ARISTOLOCHIA GIGAS.

Sir,—It may interest your Edinburgh readers to know that a very fine specimen of the curious Pelican flower, Aristolochia gigas, may at present be seen in the store behind the Palm House at the Royal Botanic Garden here.

The plant is in full vigour, and bears a number of very large curiously shaped blooms. These have a powerful offensive odour, which is most marked just after the flower opens. This odour seems to serve the purpose of attracting insects, which reach the base of the flower by climbing up a long pendant tail attached to the perianth. On the Rock Garden there is a fine bloom on a Yucca gloriosa, and Colchicum autumnale is just beginning to flower. I noticed that the roots of apparently all the Aconitum species have a peculiar allusive odour, as if some volatile sulphur compound were present. Nodules were abundant on them. Can this odour be due to them, or has any one noticed or investigated this matter? The odour is very strong in spring, when the plants are being re-potted.

Edinburgh.

J. RUTHERFORD HILL.

Answers to Correspondents, etc.

Clifford.—1. Mentha spicata. 2. Mentha sativa, var. 3. Echinum vulgare. 4. Malachium aquaticum. 5. One of the Caryophyllaceae; send a specimen in flower.

COMMUNICATIONS, LETTERS, etc., received from Messrs. Bell, Cocks, Gadd, Hill, Holmes, Morrison, Ransom.
Bragantia Wallichii.

BY DAVID HOOPER,
Government Quinologist.

"Alpam" is the name of a shrub belonging to the natural order Aristolochiaceae, growing on the western coast of Tacu. Rheede van Drakenstein, the Dutch Governor of Malabar during the latter part of the seventeenth century, seems to be the first botanist who mentions this plant, as "alpam" is figured in 'Hortus Malabaricus,' vol. vi., t. 28, published in 1686-1703. Lamarck, in the botanical portion of 'Encyclopédie Méthodique' (1783), names the plant *Apana siliqueosa*, but as Lamarck's knowledge of it was wholly derived from the 'Hortus Malabaricus,' it is most probable that *apama* is a misprint for *alpam*, and that the generic name was intended to be taken from alpam, which is now read as 'Bartolomeo,' in his 'Voyage to the East Indies,' says, "The only Malabar plant which I can with certainty call an antidote to poison is a shrub about three or four feet in height, named alpam. The root is pounded, and administered in warm water to those who have been poisoned. A Malabar proverb says, 'Alpam agatta, Vesam poratta.' As soon as the alpam root enters the body, poison leaves it. The poison referred to by this traveller is that of venomous snakes, especially cobras, which are very plentiful in the jungles of the western coast. Dr. Ainslie alludes to the plant (in 'Materia Indica,' 1826, vol. ii., p. 13) on the authority of Bartolomeo, and recommends it for further investigation, although he had not met with a specimen of the drug, and did not know its botanical origin.

Bengal and Bombay writers on Indian drugs make little or no allusion to alpam, on account of its habitat being confined to the Malabar coast and Trancanore. Dr. Dymock found the plant growing in Goa, and merely recorded what others had said about it in 'Materia Medica of Western India,' and because no authentic specimen could be obtained for description and examination, it was omitted altogether from 'Pharmacographia Indica.' Mr. M. A. Lawson, during a recent botanical tour in Trancanore, met with *Bragantia* in the hill ranges, and has placed some of the roots at my disposal.

Like other plants of this order, alpam has been supposed to have virtues in the cure of snake-bites, the juice of the leaves and the root being the parts used. Dr. Dymock has said that the whole plant, mixed with oil and reduced to an ointment, is said to be very efficacious in the treatment of pears or inveterate ulcers. The juice of the leaves mixed with Vassumbu root (*Acorus calamus*), the root itself rubbed up with lime-juice, and made into a poultice and externally applied, are the chief modes of administering it among the natives.

*Bragantia wallichii*, R. Br., is a dicoucious shrub; leaves oblong, lanceolate, three-nerved at the base, 5-8 inches by 1½-2 inches; flowers in small, irregular, few-flowered cymes; tube of perianth smooth, lobes ovate-oblong, anthers nine, trisepalous; pistil short, stigma obtuse, radiating; fruit a capsule (like a silique), slender, three to four inches long, terete; seeds one-tenth inch long, 3-gonous, deeply pitted.

There are three species of *Bragantia* natives of India and Malaya: *B. tomentosa*, Blume, possesses intense bitterness, and according to Hosfield is employed by the Javanese as an emmenagogue.

The roots of alpam are light brown in colour, knotted and twisted, about one inch in diameter at the thickest part, and tapering. The thin cortical portion is soft and corky, and may easily be removed by scraping with the finger nail. The substance of the root is tough in consistence. The odour of the bruised root is terebinthinate, and the taste nauseous, bitter. A transverse section of the root shows a rather remarkable appearance, although the peculiar structure of the wood of the aristolochias has been pointed out by Lindley, Decaisne, Von Mohl, Duchartre, and others. There are not very evident concentric zones in the wood, but it is broken up in a radiating manner into thin wedge-shaped masses extending in some instances from the cambium to the centre of the root. There is no proper pith, and the parenchymatous system is distributed in alternating layers with the wedge-shaped bundles of wood, like exaggerated medullary rays. The wood is yellowish-brown, and consists of long wood-cells, with some porous vessels running down the centre of each bundle. The parenchyma contains a large quantity of starch, and is almost white in colour.

A description of the structure of the wood of *Bragantia wallichii* with a figure of a transverse section was recorded by Dr. Maxwell Masters in a paper read before the Linnean Society about twenty years ago. The sketch of the section of the stem shows a very eccentric arrangement of the wood, with irregular zones extending laterally. This indicates a plant with a scendent habit; but Mr. Lawson's specimens were not of that character, and some sections of young stems attached to the roots of these samples showed a regular arrangement of the wood as from a round stem of an erect plant.

The powdered braganitia root yielded some yellow, tenacious, resinous substances to ether, which did not crystallise on standing. The mass heated on a water-bath to dissipate essential oil, and the residue was treated with ammonia water, which only partially dissolved some resin with a yellowish-brown colour. The alkaline mixture

---

*Bragantia wallichii.*—Transverse section of root, natural size (D.H.)
ture was shaken with ether, and the ethereal layer separated and evaporated left a soft neutral resin of a golden brown colour, giving a reddish-brown solution with sulphuric acid. The clear alkaline solution was acidified and again shaken with ether. The ethereal liquid was fluorescent, and left on evaporation a brittle, golden-brown resin acid. These resinous bodies were not analogous to aris-
tin, found by Dr. Hesse in Aristolochia argentina, by Dr. Warden in A. indica, and by myself, only lately, in A. bracteata.

After removal of resin from the powdered drug, rectified spirit extracted an alkaloid which formed a combination in the plant soluble in water. The aqueous solution of this extract, shaken with chloroform, afforded a residue containing some resinous matter with an alkaloid. The solution was then treated with ammonia, which caused a precipitate, and again shaken with chloroform. The chloroformic extract left a pinkish coloured residue consisting of impure alkaloid. This was dissolved in acetic acid, rendered alkaline with ammonia, shaken with ether, and the ethereal layer left a whitish residue of almost pure alkaloid. This base had an alkaline reaction, it gave a greenish-red solution in sulphuric acid, a yellowish one with nitric acid, destroyed the red colour of permanganate of potash, and afforded a crystalline acetate. Acidified solutions of the alkaloid gave precipitates with alkalies, insoluble in excess, also with tannin, iodine in iodide of potassium, potassio-
mercuroic iodide, potassium ferrocyanide, and phosphomolybdate of ammonium. The alkaloid and its salts were intensely bitter; it is probably allied to aristolochine, the source of bitterness in certain plants of this order.

Most of the alkaloid was removed by the spirit extraction, only a small quantity remaining in the extract subsequently made with water. The watery extract also contained a substance which reduced Fehling’s test, and on allowing the evaporated ex-
tract to stand for some weeks, some hard, white, transparent crystals separated out, which were related to dulcite.

The following table gives the results of the ex-
amination of the powdered root of Bruguiera salicifolia or "alpam.

| Neutral and acid resins, and ext./by ether | 1-48 |
| Alkaloid, etc., ext./by spirit | 3-43 |
| Water extract | 6-71 |
| Starch and fibre | 77-02 |
| Ash | 3-35 |
| Moisture, etc. | 8-01 |

Recent Work in Botany.

Classification of Plant Tissues.*

The method according to which English botanists have been accustomed to classify plant tissues until quite recently is that proposed by Sachs, the three systems of tissue recognised being the dermal, fascicular, and fundamental or ground tissue. This arrangement is not a strictly morphological one, and is only to a limited extent physiological. A scientific morphology must be founded on development, whereas Sachs and De Bary classify

the forms of tissue by purely histological characters, i.e., according to the mature structure of their elements. The lack of a natural grouping in De Bary’s book tends to give the impression that anatomy is nothing but an accumulation of detail, and that a morphology of the tissues, based on homology, and comparable to that of external organs, does not exist. However, recent attempts to found an internal morphology of plants, though as yet only partially successful, have given new life to the study of botany.

The recent progress in this direction is mainly due to Van Tienh, the French botanist, the characteristic feature of whose anatomical teaching is the recognition of the central cylinder or “stèle” as a definite region comparable to cortex and epidermis. In the root the central cylinder is perfectly well defined, including within it the ring of alternating bundles of wood and bast, accompanied by a certain amount of parenchyma (conjunc-
vuitive tissue), the outer layer of which constitutes the pericycle, or limiting layer of the stele. The cortex, the inner layer of which is the endodermis, surrounds the stele, and outside the cortex is the pelliferous layer or epidermis.

The same three regions—central cylinder, cortex, and epidermis—exist in the stem. The stele is made up of the vascular bundles and conjunctive tissue, the latter constituting the pith, primary medullary rays, and pericycle. The last-named is often less obvious than in the root, but is charac-
terised by the same power of forming new tissues and organs. At every node the continuity of the main stele is interrupted, and its limits may be difficult to recognise, but it is none the less a distinct region in the stem because it possesses pro-
longations into the leaves. Where the vascular bundles bend out from the stem into the leaf, they are accompanied by conjunctive tissue, and the name “meristele” is applied by Van Tienh to such a bundle or group of bundles entering a leaf, with their enveloping conjunctive tissue. Thus, the stelic tissue of the whole plant is seen to be continuous through all its organs—root, stem, and leaf.

In the typical stems of Phanerogams there is a single central cylinder in direct continuation with that of the main root. This “monostele” condition is constant in the embryonic stem of all vascular plants. But in many vascular Cryptogams and in the genera Gunnera and Primula, section Auricula, the cylinder divides up above the hypocotyl or first stage of the stem, a number of equivalent steles thus resulting. In most Ferns, and in many Selaginellas, this “polystely” occurs. The modifications of polystelic structure in detail may be studied in Vines’ ‘Students’ Text-Book of Botany’ (Sonnenachse), where the views of Van Tienh have lately been embodied.

"Aestely” or “schizostely” is a departure from typical structure characterised by the stele completely breaking up into the individual bundles, each surrounded by its own “peridem” (the conjunctive tissue at the periphery of any portion of a sub-divided stele, as distinguished from the peri-
cycle which surrounds an entire stele) and endo-
dermis. Typical examples occur in Equisetum limosum and other species, in Nymphaea and aquatic species of Ranunculus, etc.
NOTES ON RHUBARB.*
BY BARNARD S. PROCTOR.

This paper has for its object the putting together into a connected form the various points of pharmaceutical interest concerning rhubarb which have been noted from time to time by the writer, together with such additional experimental results, more recently obtained, as the evident gaps in the old matter made necessary.

The question arose as to the advantage or otherwise of trimming rhubarb root, and after numerous experiments the general conclusion came to from the results was that the removal of the dark coloured outer portion of the root ought not to be countenanced, since that portion is richer than the interior in the alcohol-soluble extractive matters upon which the medicinal value of the root depends.

The following are the results of the action of different solvents upon the root:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Extracted by rectified spirit.</td>
<td>36.0</td>
<td>30.0</td>
</tr>
<tr>
<td>HCl and proof spirit</td>
<td>16.0</td>
<td>17.0</td>
</tr>
<tr>
<td>Extracted by KH0 and water</td>
<td>20.5</td>
<td>25.0</td>
</tr>
<tr>
<td>Insoluble residue</td>
<td>21.5</td>
<td>27.0</td>
</tr>
</tbody>
</table>

It also follows that, in judging of the quality of commercial powdered rhubarb, the brightness or paleness of colour, which may indicate the absence of decayed roots, may also indicate low percentage of active constituents and a high percentage of calcium oxalate.

The examination of a sample of good commercial Chinese rhubarb root, supplied from the Pharmaceutical Society's museum by Mr. E. M. Holmes, showed a remarkably close correspondence between its exterior and interior portions, the following results being obtained:

<table>
<thead>
<tr>
<th>Extracting Medium.</th>
<th>Exterior.</th>
<th>Interior.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Strong spirit</td>
<td>39.00</td>
<td>42.70</td>
</tr>
<tr>
<td>Spirit, 2; water, 1</td>
<td>8.60</td>
<td>5.05</td>
</tr>
<tr>
<td>Spirit, 1; water, 2</td>
<td>1.26</td>
<td>1.00</td>
</tr>
<tr>
<td>Cold water</td>
<td>0.60</td>
<td>0.90</td>
</tr>
</tbody>
</table>

These results, however, together with those of Dragnendorff, show that there appears to be very little prospect of securing any sharp separation or determination of the proximate constituents of the root by the use of a series of solvents.

Experiments in decocition rhubarb show that the odorous matter can be removed by chloroform, constituting an oily extract, but after this treatment the rhubarb seems to have the power of developing more of the odorous principle, by the action of air and moisture upon it.

The almost total absence of oil in unpowdered rhubarb root is a point readily ascertainable by the pharmacist and worthy of his attention. The addition of a small quantity of oil in grinding facilitates the production of a smooth powder and a bright colour, but this is scarcely to be regarded as an adulteration. At the same time a fat exists in the root to the extent, in the Chinese rhubarb examined, of 0.66 per cent. Turmeric is not likely to be found in the rhubarb of pharmacy. Chrysophanic acid is present in both fresh and dried rhubarb, and when it is removed from the powder by means of benzol, a further development of the acid may take place on exposure of the exhausted powder to the action of air, water, and caustic potash.

A consideration of the constituents of rhubarb and their solubilities suggests that a tincture prepared with strong spirit would contain the chrysophan and tannin, accompanied by little or no cathartic acid, whilst a proof spirit tincture should contain all that is active. Again, an extract prepared by distilling off the spirit from this proof spirit tincture would possess rather more medicinal value than the official extract, from the exclusion of inert gum.

The solubility of the cathartic acid is such as permits its extraction by spirit about thirty over proof, but that is about the extreme strength available. Weaker spirit is not available for percolating a fine powder, and a coarse powder is more difficult of exhaustion. In the case of the B.P. syrup the use of weak spirit and a coarse powder results in the solution of matter which induces a tendency to fermentation.

The addition of a strong tincture, made with proof spirit or spirit twenty to thirty over proof, to simple syrup is an improvement on the official formula.

Problems of interest arising out of the work that has so far been done concern the nature of chrysophanic and cathartic acids; the proportion of oxallic acid to lime in the ash of rhubarb; and the influence of maturity of the root at gathering, and of long keeping after collection, upon the quantity of fat and chrysophanic acid.

THE ANALYSIS OF MALT.*
BY JOHN A. MILLER, PH.D.
(Concluded from p. 194).

METHOD NO. III.

Fifty grammes of ground malt are weighed out as rapidly as possible, then placed in a weighed copper beaker and mixed with 200 C.c. of water at a temperature of 40° C. The whole mixture is then carefully heated on an asbestos plate until the immersed thermometer registers 60° C. This temperature of 60° C. is maintained for twenty minutes, the mixture being almost constantly stirred during this time. At the end of twenty minutes a few drops of the solution are tested with iodine solution in order to ascertain whether the saccharification is complete. If the iodine gives the starch or erythrodextrin reaction the mash is further heated, the temperature being carefully raised 1° every two minutes until iodine solution ceases to give any reaction. It is very seldom that the temperature will go above 70° C. The flame is then removed, the mash cooled down, and

* From the Journal of the American Chemical Society

* Abstract of a paper submitted at the Oxford meeting of the British Pharmaceutical Conference.
enough water added to make the total amount used equal to 400 grammes, or the weight of the mash, that is, the malt plus the water equal 450 grammes. After thoroughly mixing, the mash is thrown upon a platted filter. The first half of the wort which filters through is thrown back upon the filter, and then all which filters through collected. The specific gravity of this filtrate, or wort, is then taken by means of the Westphal balance. From this gravity the percentage given by Schultze's tables is ascertained, and that number multiplied by 8.75, which gives the percentage of dry extract yield from the malt. The percentage can also be calculated by the use of the following formula:

\[(900 \times \text{per cent. water}) \times \text{per cent. Schultze} \times 100 \times \text{per cent. Schultze.}\]

The Schultze tables are so arranged that they give the amount of extract in 100 grammes of wort of the specific gravity obtained. It would be a natural conclusion that the percentage represented by Schultze tables should be multiplied by 8 in order to obtain the amount of extract in 100 grammes of malt, but this factor gives results which are below the absolute amount of extract which may be obtained from the malt. As the result of actual brewing experience, I am of the opinion that the percentage Schultze multiplied by the factor 8 represents the amount of extract which the average brewer obtains from his material in actual practice, although the absolute amount obtainable on a small scale is higher. Two mashes of fifty grammes each gave:

<table>
<thead>
<tr>
<th>I.</th>
<th>II.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specific gravity of wort</td>
<td>1.0285</td>
</tr>
<tr>
<td>Extract calculated</td>
<td></td>
</tr>
<tr>
<td>from Schultze's table</td>
<td>58.96 p.c.</td>
</tr>
<tr>
<td>Factor 8.75</td>
<td>64.487</td>
</tr>
<tr>
<td>Extract calculated by formula</td>
<td>64.24</td>
</tr>
</tbody>
</table>

5-1425 grammes of this wort were placed in a flat-bottomed plate and dried at 105°C to almost constant weight. Results, viz.:

<table>
<thead>
<tr>
<th>I.</th>
<th>II.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weight of extract</td>
<td>0.3511 grammes</td>
</tr>
<tr>
<td>Average weight of extract</td>
<td>0.3502 grammes</td>
</tr>
<tr>
<td>Extract</td>
<td>56.03 per cent.</td>
</tr>
</tbody>
</table>

The same amount dried at 70°-75°C for about seventy hours to constant weight gave:

<table>
<thead>
<tr>
<th>I.</th>
<th>II.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weight of extract</td>
<td>0.3700 grammes</td>
</tr>
<tr>
<td>Average weight</td>
<td>0.3690 gramme</td>
</tr>
<tr>
<td>Extract</td>
<td>59.04 per cent.</td>
</tr>
</tbody>
</table>

In order to ascertain what variation, if any, existed between these results and the absolute amount of extract obtainable, I made another mash from the same sample of malt which had been used for the preceding experiments. Method No. III. was used with this exception, that it was not made up to 400 grammes, but was at once thrown upon a filter and washed with water at a temperature of 58°C, until the filtrate gave no reaction for sugar with Fehling's solution. This filtrate was then made up to 1000 C.c. and an aliquot part dried at 70°-75°C to constant weight. Two portions of 10 C.c. each gave:

<table>
<thead>
<tr>
<th>I.</th>
<th>II.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extract by weight in 10 C.C.</td>
<td>0.3237 grammes</td>
</tr>
<tr>
<td>Extract in 1000 C.C.</td>
<td>32.37</td>
</tr>
<tr>
<td>Percentage of extract from malt</td>
<td>64.74</td>
</tr>
<tr>
<td>Average percentage</td>
<td>64.73</td>
</tr>
</tbody>
</table>

The variations existing between the results obtained is apparent in the following table:

<table>
<thead>
<tr>
<th>No. I.</th>
<th>No. II.</th>
<th>No. III.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Per cent. of extract calculated according to the directions of the method.</td>
<td>59.01</td>
<td>63.85</td>
</tr>
<tr>
<td>Method III using factor 8...</td>
<td>58.96</td>
<td>64.24</td>
</tr>
<tr>
<td>Extract dried at 105°C...</td>
<td>58.87</td>
<td>54.25</td>
</tr>
<tr>
<td>70°-75°C...</td>
<td>58.99</td>
<td>59.07</td>
</tr>
<tr>
<td>Absolute per cent. of extract obtainable...</td>
<td>64.73</td>
<td></td>
</tr>
</tbody>
</table>

A comparison of these results shows that methods II. and III. give us figures agreeing closer to the actual amount of extract obtainable from the malt than method No. I., but even these are a little below the actual content. No. III., however, only slightly so. The results obtained by drying at 105°C are too low and untrustworthy owing to a decomposition during the process of drying, as will be shown later in this paper. Looking at the results of the three methods as obtained by drying the extract at 70°-75°, we find an excellent agreement between the maximum and minimum results, but a wide variation from the absolute amount of extract. This would indicate that a marked amount of starch was not saccharified, and consequently would be lost as extract. It was only obtained by the washing of the grains in warm water.

Extract dried at 105°C.—In order to ascertain why the extract dried at 105°C was so much lower than when calculated or dried at 70°-75°, a malt analysis was made with the following results:

<table>
<thead>
<tr>
<th>Method III.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Calculated per cent. of extract using factor 8</td>
</tr>
<tr>
<td>Extract dried at 70°-75°C...</td>
</tr>
<tr>
<td>105°C...</td>
</tr>
</tbody>
</table>

The percentage of extract obtained by drying at 105°C is over 4 per cent. lower than the percentage of extract obtained by the other methods. This would indicate that either the percentage of extract was actually lower than indicated by the other methods of determination, or that some substance had undergone decomposition and occasioned a loss which reduced the percentage. I was of the belief that the maltose had suffered decomposition at the temperature of 105°C, and therefore lowered the percentage of extract.

Determinations of sugar were consequently made:

1. In the wort obtained by method III. and calculated to the total amount of extract obtained.
2. The maltose or sugar contained in the extract dried at 70°-75° was determined and a calculation made for the total from these results.
3. The sugar contained in the extract dried at 105°C was determined and a similar calculation made.
CONCLUSIONS.

1. Methods II. and III. give results almost equal in accuracy, No. III. giving nearer the absolute amount of extract obtainable when the factor 8.75 is used. It is furthermore a preferable method, as it requires less time for the analysis than No. II. And where a number of samples are handled, time is an important item.

2. Method I. is inaccurate, as the results obtained are much below the actual amount of extract.

3. The extract cannot be determined by drying at 105° owing to the decomposition of the maltose at that temperature. This applies to the determination of extract in beer as well as in unfermented worts.

4. The washing of the grains until no sugar reaction is obtained and the subsequent drying of the extract at 70°-75° C. is impracticable, except for scientific purposes, as the amount of time required for the completion of an analysis is too great.

I would recommend method III. as the simplest; it is accurate when the factor 8.75 is used, and requires the least time. It is the method upon which a subsequent paper on diastatic power will be based.

I wish, here, to express my sincere thanks to my assistant, Mr. W. I. Tibble, for the very able and enthusiastic manner in which he has assisted me in this investigation.

LIQUORICE TRADE OF BATAUM, RUSSIA.

The liquorice root trade with America appears to be on the steady increase. Out of the total quantity of root and paste shipped from Batoum in 1893, 16,720 tons were forwarded to the United States, the balance of 1186 tons being shipped to England and France. Out of the latter-mentioned quantity only about 500 tons were paste and the rest pressed roots. Over-production has brought about more or less of a crisis in this trade, and about 14s. 7d. was being paid towards the end of the year to the peasantry for every ton of root delivered at the factories in the governments of Baku and Elisavetpol. The result was that little or no root was being collected by the natives, and I understand that in consequence of the large quantities of pressed roots in stock, two out of the three root-pressing works of the Caucasus remained inactive during a portion of the past year.—Consular Report.

ANTOINE-LAURENT LAVOISIER.*

BY WILLIAM B. THOMPSON.

The close of the last and the dawn of the present century form important epochs in the history of the science of chemistry. The mark of a period lies in the history of its scientific men. These are the centres and sources from which spring development and intellectual progress, and it is truly well for us to gauge the measure of our gain in a faithful retrospect of the life-work of those who have wrought out to demonstration, truths which time and experience expand into the fulness of knowledge.

The mysticism of alchemy had long been laid aside for the light of a truer wisdom—advancing civilisation aroused and demanded a spirit of inquiry—speculation yielded to investigation—a flame had been kindled—diligence and patience brought their votaries to the task, and the roll of fame is honoured in its inscriptions—Black, Cavendish, Priestley, Scheele, Lavoisier, each of which adds lustre to the sun of human achievement. The fame of these lies in our keeping, and what they have given to the store of knowledge is in part our heritage, of which we should show ourselves to be worthy—worthy in the respect which shall ever be paid to honoured memories, and in the homage of future generations at the shrine of science.

The more fully the histories of these illustrious men become comprehended, the more eager will be posterity to accord the fullest measure of justice to their individual worth, and to the inestimable advantages their discoveries have imparted to human life and to human happiness. The present memoir has, however, particular reference to Lavoisier—Antoine-Laurent Lavoisier—the centenary of whose tragic death has just lapsed, and just been recorded. A corrupted tribunal and the fury of a Parisian mob consigned him and twenty-seven of his associates to death at the guillotine, in one day, in May, 1794. Thus died, at the age of fifty-one, one who was conspicuously ardent and enthusiastic in the pursuit of knowledge, noble and aspiring in all desires and purposes, devoting an active life to humane and unselfish pursuits. The political situation of France at that time was deplorable in the extreme—recklessness and profligacy ruled the hour. Lavoisier's fatal blunder lay in his acceptance of a political position. The faults with which he was charged were those of his associates, not his. His personal record was above reproach, yet innocence was sacrificed to appease the ranour of jealousy and hate; and in order to show the vindictive spirit which prevailed, Coflinhal, who presided at the trial, is said to have exclaimed, when a plea for Lavoisier was offered, "France has no need for men of science!" The deep darkness of ignorance had not been dispelled a hundred years ago. There were many reasons why France should have exulted in the fame of her philosopher, Lavoisier. At the zenith his name became a word of national fame. Yet, passion and fury held such sway over the minds of evil-disposed men, that it required but the momentary descent of

* Reprinted from the American Journal of Pharmacy.
the glittering axe to strike off a hand that not even a hundred years will suffice to replace with an equal. The ignominy of death destroys not—the name of Lavosier will ever remain dominant in the chemical world of the last century. This man rendered inestimable service to his country and to mankind. He was guided and governed by an intellectual philanthropy. He was distinguished as an academician and an economist. He devoted a high order of talent to agricultural chemistry, and gave to his countrymen a knowledge to be practically applied in the cultivation and fruition of the soil. Lavosier was born on August 26, 1748, at Paris, the same decade of years which ushered in his eminent contemporaries, Priestley and Scheele. His preceptors were the Abbe La Callie in mathematics, Bernard de Jussieu in botany, and Gueyraud in geology and mineralogy—a trio distinguished in science. Lavosier's first manuscript essay (1765) was upon the subject of calcium sulphate, or gypsum. This was chiefly noteworthy in giving for the first time an explanation of the "setting" or hardening of plaster of paris; also noting the chemical alteration in an over-burnt product. The following year he was awarded a medal by the "Academie des Sciences" for the merit of a plan for illuminating large towns. He became a candidate for election to the august body of the Academy, and on May 18, 1768, gained the privilege of a seat on the rear bench. This was in the thick of the dark and stormy days of the Revolution. Yet, amid profoundly disturbing causes, Lavosier found time to pursue his themes, and during his twenty-five years of connection with the Academy he contributed over two hundred reports upon various and miscellaneous subjects. These covered a wide range in science and natural philosophy. His varied positions of public life and trust, and more especially during his term as fermier general (a state official controlling the financial system), he became deeply interested in the condition of the peasantry of France, in their agricultural employments and interests. He drew up exhaustive treatises on the cultivation of flax and of the potato, and of the timing of wheat. He established working plans for experimental farms, where methods in cultivation could be demonstrated as well as taught, established depots for the collection of agricultural implements, and codes for the more equal adjustment of tithes and taxes and rentals; also rights in pasturage. The economic condition of agriculture in France at that time had become extremely wretched—impoverishment everywhere. Farmers had but few beasts; the winter food of cattle was provided in many districts; fields were unfertilised; the yield of corn was not greater than five times the weight of the seed. Lavosier sought, patriotically, through his knowledge, to remedy these distressing evils. He introduced the cultivation of the beet and potato; he improved and increased the breed of sheep and of cows. Under this wise foresight and philanthropic effort each succeeding year marked a change for the better in the lot of the peasant. In 1793 the crop of wheat had doubled; the number of beasts had increased five-fold. Yet, withal, in the following year, Lavosier died the death of ignominy at the hands of those whom he had spent his life in befriending and benefiting—wicked, monstrous ingratitude! He was made a victim of popular prejudice, and was an unfortunate citizen of a crumbling, rotten, and hopelessly fallen dynasty. Lavosier was the author of savings and discount banks, workhouses, insurance societies, establishments for the tutoring of nurses, plans for the formation of canals, and for exploiting the mineral resources of the country.

Thus is presented a history of a brief life, yet that of one thoroughly imbued with the ardour of his nationality—a man of intense zeal and large philanthropic purpose. The gifts of his mind were generously and bountifully given for the benefit of his race. His varied knowledge had no selfish application. He appears to have pursued and investigated truth for the sake of truth. His life is a lesson for the studious. In philosophy and science there is no brighter or more illustrious exemplar than Lavosier. Let his name be for ever honoured and revered!

WHY NOT TURN YOUR KNOWLEDGE TO ACCOUNT? BY FRANK EDM.

The pharmacist is often called upon to dispense odd chemicals, and if he were to keep anything like the assortment in stock that he may have calls for occasionally, he would soon find his shelves stored with goods, in some instances likely to spoil, and in others to be unsaleable. It is astonishing how often pharmacists let customers go without once remembering that on their shelves are all the chemicals necessary to produce easily and simply the required article. And if a given substance is wanted in the form of solution, its preparation often would require but a minute.

The pharmacist, by so doing, can easily make a reputation for himself in the manufacture of these goods, and one can often hear people say, "We will go to So and So's pharmacy, for if he hasn't got it in stock, he will make it for us." It is astonishing how soon such things become known, and when known, what a powerful influence they are towards building up a tradesman's business.

The writer calls to mind an instance of a physician who, after going the rounds of the stores, inquiring for sub-lodide of bismuth, came to the establishment where he was employed, and inquired for the article. He was told that it was not in stock, but could be made for him within a certain time. At another time he wanted iodide of calcium, and then saccharated iodide of iron, and thus became a regular customer. Another time, a certain photographer came in and asked for chloride of lead and sulphate of lead. He was told that they were not in stock, but would be made for him. This gentleman afterwards took particular pains to send people to the store.

Elsewhere, in an article on the remedy for the speciality nuisance, the writer has said that there is no place where a pharmacist can so easily make a reputation for himself, no place where he can occupy his spare time to so much advantage as in laboratory
work. And this work can be done without neglecting the mercantile part of his business. It is not the purpose of this article to advocate the making of chemicals in the drug store, for the reason that in most cases they can be purchased from reputable manufacturers for as little money as they can be made for by the pharmacist. And, therefore, there is no argument in favour of making them on the ground of economy.

But with odd chemicals it is different. The pharmacist cannot afford to buy them, for the sale would not justify it, and in most instances they can be prepared from those chemicals carried in stock, and many of them can easily be made. Take, for instance the lithium salts. Having the carbonate of lithium in stock, the pharmacist is able to supply the citrate, salicylate, benzoate, borate, etc., if in solution, in a few minutes. And he can, also, easily prepare the salts themselves when so desired. The same is true of the ammonium salts, also of those of potassium and sodium.

Some years ago, while employed in a pharmacy where many prescriptions calling for solution of benzoate of ammonium, ten grains to each draught, were filled, the writer had his attention called to the insolubility of the preparation as sold in the market. This was entirely due to the salt being of acid reaction instead of alkaline, as directed in the pharmacopoeia. Of course, solution could be effected by heat, but it would crystallise out when cold. This difficulty was remedied by adding ammonia in slight excess. In order to overcome the trouble, a permanent stock solution was made up, containing ten grains to the draught. This solution was made by taking the proper amount of benzoic acid and water, applying heat, and adding ammonia to slight excess, filtering, and adding water to make the proper volume. Thus we were able to dispense these prescriptions rapidly and properly. It is an old practice, and a good one, to keep a 50 per cent, solution of potassium acetate on hand for dispensing. Such a solution keeps well, and is easily made.

It is astonishing what a number of chemicals the pharmacist can prepare himself, with comparative ease, if he will consult his reference works. Such work makes him a better pharmacist, and gives him a more accurate and practical knowledge of chemical processes and the chemistry of what chemicals he handles. In fact, there is no line of work so conducive to the actual thoroughness of the pharmacist as this. It enables him better to understand the action of one chemical upon another, and to forecast results of combinations ordered in prescriptions, and often to save physicians from serious error. Again, it gives a clear and more practical insight into the arithmetic of chemistry, and in every way conduces to the benefit of the pharmacist. And the good which comes from this line of work is the advantage it is to the apprentice. He thus becomes familiar with working-methods, and it is of great advantage to him. Seeing practical demonstrations of what pharmacy should be, he is better able to appreciate the teachings of the schools.

ON CITRIC ACID FERMENTATION.*

BY DR. C. WEREMER,

Hyphomycetes are, as well as other fungi, able to effect fermentations under certain circumstances. A process of this kind, by which as much as one-half of the sugar used is converted into oxalic acid, is well known. I made this process, hitherto the only acid fermentation induced by Hyphomycetes, the subject of a more elaborate investigation.

Further research has brought to light another case similar to oxalic acid fermentation in many ways, the product of which is another organic acid not hitherto obtained under such conditions. I call it "citric acid fermentation."

Certain moulds possess the property of converting a considerable proportion of the sugar contained in the nutritive solution into an organic acid which is, in constitution and properties, identical with that found in lemons, and can be obtained easily and abundantly in well-formed crystals. The nutritive solution becomes very acid after a little time, and the amount reaches 5 per cent, and more. Experiments on a larger scale yielded the acid in such considerable quantities that the commercial application of the method promises to be successful.†

The fungi which effect the fermentation are microscopically hardly to be distinguished from the well known Pennicillium glaucum. They form densely interwoven green films of so energetic a growth as to spread over the largest surfaces in a few days’ time. Compared with Penicillium they are distinguished, amongst other things, by the structure of the condidiophores; otherwise they are closely allied to it, though the discussion of their systematic position must be deferred owing to our incomplete knowledge of their development.

The more exact examination of the two very similar species proved that they were hitherto undescribed. It was not possible to refer them to the general Penicillium, Eurotium, or Aspergillus, as they are defined at present. Thus the creation of a new genus was expedient, and I propose the name Citromycyes for it. I call the more completely known species, to which a third will probably be added, Citromycyes glaucernus and Citromycyes glaber.

The spores of these fungi are found to be rather common in the air. Placed on suitable substrata they soon develop into white tufts, which, however, are usually soon overgrown by other species (Penicillium) hence it is somewhat difficult to obtain pure cultivations. They may be often met with on fluids containing sugar, or on fruits, particularly acid ones.

I may briefly point out a few details relating to the process of acidification in respect to the development of the fungus, the substratum, temperature, and supply of oxygen.

Solutions of sugar containing the necessary nutritive

--- Western Druggist.

* Condensed translation of a communication to the Berlin Academy. Reprinted from the Kern Bulletin.
† Artificial citric acid is already produced on a large scale, and by a method based upon what is stated here, by the Fabriques de Produits Chimiques de Thann et de Mulhouse, at Thann, in Elzas.
material present the most favourable conditions for its growth, as well as for the formation of the acid; both, however, are independent of each other, though their optimums of temperature approximately coincide.

But the formation of acid can take place beyond the maximum of growth, whilst, on the other hand, the growth of the fungus can proceed without the formation of acid. Temperature is a condition as important to the process as the chemical constitution of the substrate and the presence of sufficient oxygen; for it is not the limited access of oxygen which induces the accumulation of acid. It is not, however, possible at present to be certain whether the carbonic acid set free does not affect the fungus injuriously; there are indications that it does. At all events, absence of air soon brings the vital phenomena to a standstill, and in an atmosphere of carbonic acid neither germination of conidia nor any further development takes place. Lights, however, is of no importance; germination, growth, formation of conidia, and acidification take place at an unaltered rate in absolute darkness.

Although citric acid, when present in quantities of several per cent., is rather beneficial than otherwise to the growth of the fungus, which can endure as much as 10-20 per cent., the presence of inorganic acids on the other hand is extremely injurious, and they restrict the growth of the mycelium to a very slow rate, even when present in mere traces.

As in other well-known cases of fermentation, a further production of acid may be obtained by precipitating that already formed. Thus, it is easy to convert as much as one-half of the sugar used into acid; 30 grammes of dextrose yielded about 16 grammes of acid. By this means, the conversion is also accelerated, and the breaking-up of the sugar, with which the formation of acid is evidently closely connected, proceeds more rapidly. Other agents may also act in a similar way, as, for instance, the presence of saline compounds of chlorine, etc. The formation of acid continues as long as there is any vitality in the fungus film and available material in the liquid. The acid, however, which is found in the fermenting fluid at a given time, is the residue which results from the two parallel processes of acid formation and acid destruction; the latter eventually prevails, and finally every trace disappears in older cultivations. The destruction of the acid by the fungus is easy to prove by experiment.

By precipitating the acid in the form of a stable salt we eliminate the destructive agency, and favour, at the same time, the causes which favour the accumulation of the acid; this method gives a more exact idea of the process of acidification. It is found to be by no means continuous and uniform at different times, but its rate describes a rather suddenly ascending and descending curve, which is in close relation to the amount of the conversion of sugar effected by the growing fungus.

The formation of the acid proceeds most actively at the time of maximum vitality of the fungus-film; it increases before and decreases after this period.

I may point to the rather interesting comparison with the production of oxalic acid. In this, favourable conditions of fungus growth (heat and presence of chlorine compounds) promote the rapid destruction of the acid, and prevents its accumulation in the cultivations. Under similar conditions the production of citric acid is not only not checked, but even advanced. The difference may perhaps depend on the lesser capacity of citric acid for being oxidised.

The comparison is important also in other respects. As much as one-half of the sugar consumed can be converted into oxalic acid without impairing the fungus growth. In the production of citric acid, the withdrawal of very considerable quantities of this acid has actually no demonstrable influence on the development of the fungus. We must therefore regard the citric acid as a product of metabolism, to which the fungus is comparatively indifferent. It is, however, evident that when with a given production of fungus material one-half of the consumed sugar is precipitated as citric acid, the other accessory product must decrease in quantity. In this instance this is the carbonic acid into which also under other conditions part of the citric acid is converted. The question now is whether the relation is a direct one. On the whole, I should, taking into consideration the observations of O. Warburg on Crassulaceae, rather prefer this view to other hypotheses. The breaking up of the sugar molecule results in a great deal of the citric acid produced, besides perhaps other compounds, yielding ultimately carbonic acid as a product of oxidation. Although we may thus consider the acid actually liberated as an intermediate product of metabolism, we leave the question of its constant presence with our fungi undecided, though possible. I may mention, by the way, that oxalic acid occasionally appears in the fermentative process. But there is no necessity to trace back the totality of the material broken up by metabolism, especially the whole of the carbonic acid derived from respiration, to molecules of organised living substance.

A closer study of the metabolism in this direction might throw light on the process of respiration; for mere determination of carbonic acid without considering other conditions cannot naturally explain it.

Finally, I must point to the constitution of citric acid as having an important bearing on the theory of these fermentative processes. It is clear that it cannot be regarded as a direct product of sugar-oxidation.

CAMPHOR TRADE OF TAMSUI, CHINA.

The trade in this product is rapidly growing in importance. The export in 1893 was much the largest on record, and more than double that of the previous year, amounting to 32,134 cwt., against 15,440 cwt. for 1892, which total, however, in consequence of disturbances on the border, was smaller than in 1891. To all appearance this branch of business is destined to increase still more in the near future, especially if certain difficulties which somewhat detract from the market value of Formosa camphor as compared with the Japanese product can be overcome.—Consular Report.
The Congress at Budapest.

The pharmacy section of the Congress was opened in due form on the 3rd inst. by Dr. Gyula Jarmai, the President, upwards of fifty members being present on that occasion. In his opening address Dr. Jarmai referred to the establishment of an independent section of pharmacy as being an appropriate indication of the fact that there is an intimate relation between the pharmacist’s art and the work now being done to promote public health. He congratulated his colleagues on the opportunity thus offered for extending their sphere of usefulness to the community, and on behalf of the pharmacists of Budapest heartily welcomed the foreign visitors.

The first paper read was by an Hungarian pharmacist, Herr Gallik, dealing with the appointment of pharmacists as public analysts. It was urged that their technical experience and qualifications specially fitted them for the work of examining articles of food and drink. That view was very generally adopted in the discussion which followed. Professor Belohoubek and others suggested that in view of such appointments being made the educational training of pharmacists in chemical analysis should be suitably extended. A resolution was unanimously passed by the section to this effect. At the subsequent plenary meeting of the Congress, when the sectional resolutions were brought up for confirmation, this resolution was rejected in consequence of a representation by Professor Comfield that no one who understood the difficult and delicate nature of the work to be carried out in the analysis of articles of food would entrust it to dispensing chemists. This peculiarly British view of the matter seems to have carried more weight than it was entitled to have at an international congress. It appears also to have been put forward as an objection to the resolution passed by the pharmacy section without sufficient appreciation of the proviso that adequate chemical training for the duty was a condition recognised as necessary. But the plenary sitting of the Congress was altogether the least satisfactory part of the proceedings, having been very poorly attended, besides being wanting in many other respects. The opinion expressed by the pharmacy section of the Congress as to the appointment of pharmacists as public analysts is in full accordance with the view held on this subject in Germany and France, and it does not in any degree leave out of consideration the necessity of full scientific qualification on the part of those entrusted with the important duties attaching to the office of public analyst.

The next subject brought forward at the pharmacy section of the Congress was the international pharmacopoeia. Papers were read by Herr Christomanos, of Athens, and Professor Vulpius, suggesting that a new committee should be appointed to carry out the work, and that application should be made to the governmental authorities of different countries for assistance in its execution. Herr von Waldheim reported what has already been done in this direction, and showed that the three principal objects to be aimed at are the adoption of an absolutely definite, nomenclature uniformity of methods of preparation, and uniform strength of pharmacopoeia preparations. With the fullest attention of those objects, in regard to potent preparations, the aim of a universal pharmacopoeia would be secured. But he regards that result as a work of time that can only be brought about by agreement among the members of the committees entrusted with the preparation of pharmacopoeias in different countries. He disapproved of the proposal to solicit assistance from the governments as being impractical, and thought that the end in view might be better accomplished by pharmacists relying upon their own capabilities and mutual agreement. After a long discussion it was finally decided by a large majority that the committee appointed by the Congress in London in 1881, including representatives of all countries, should be requested to continue its work, and take such further steps as may be deemed advisable.

At the second sitting of the section, papers were read on the subject of the inspection and control of pharmaceutical establishments, which were of interest more especially in relation to the conditions obtaining in continental countries. Herr Heges, of Vienna, read a paper describing the usages of different countries in regard to the establishment of pharmacies, and Herr Gallik one on different systems of control. The remainder of this and
the concluding sitting of the section were occupied
with the reading of papers relating to various
subjects of pharmaceutical interest, the conserva-
tion of drugs, the methods of testing adopted in
the Hungarian pharmacopoeia, and the apparatus
most suitable for the purpose.
After the close of the second sitting of the section
the foreign visitors were very hospitably entertained
at dinner by the members of the Pharmaceutical
Society of Budapest. The chair was occupied by
Dr. Jarmay, who, together with Herr Tészók and
the other members of the Sectional Committee
were, on that occasion and throughout the whole
of the Congress, indefatigable in their efforts to do
honour to their guests and afford them every
facility for becoming acquainted with each other
and with the numerous attractions of
their beautiful city. Though upwards of two
hundred persons were present at this dinner,
its contrasted favourably with some of the other
entertainments connected with the Congress, which
were of a more tumultuous nature, as, for instance,
an excursion to the wells from which the Hunyadi-
János water is obtained, and the reception at the
museum at the commencement of the Congress,
which furnished material for satirical comment by
the local comic papers. But it was the guests
rather than the hosts who were responsible for the
objectionable features of those gatherings, unless,
indeed, excess of hospitality may be regarded as an
excuse for the former. One of the most delightful
excursions was that to an estate of Count Nicolas
Estrenhazy, about two hundred thousand acres in
extent, where a large party was most hospitably
entertained during the day, and had an opportunity
of witnessing the more than regal state character-
istic of the every-day life of an Hungarian
magnate.

THE SALE OF MEDICINAL PREPARATIONS
CONTAINING POISON.

Under this heading, three weeks ago we re-
furred to the opinions expressed by the organ
of the manufacturers of stamped proprietary
medicines, on the result of the late appeal, and
quoted the editor's advice that grocers should ab-
stain in future from vending medicinal preparations
containing scheduled poisons as ingredients. In
the Grocer for last week the subject is con-
sidered from the unqualified dealers' point of
view, and with evident reluctance to accept the
petition as defined by the judges in the Court of
Appeal. Though it is acknowledged that at each
stage of the Armson case it was clearly held that
the article in dispute could only be sold by
registered chemists, and though the decision has
been arrived at not to make further appeal to the
House of Lords, it is stated to be yet
undecided whether the question will again be
fought in regard to the particular article to
which that case referred. "Some of the
more enthusiastic now believe that the contest
between the grocers and the chemists is thus
over; and they say that the law has now stated
that only registered chemists and druggists may
sell or keep open shop for selling proprietary
articles that contain an 'appreciable' amount of
poison. But what is an 'appreciable' amount? According to the Armson case, one-tenth of a
grain in a fluid ounce is such a quantity. On the
other hand, in the Delve case, an 'infinitesimal'
amount in a proprietary medicine does not limit its
sale. But how is the seller of these goods to know
what poison, and how much of it, is in any given
medicine? The trade may call upon the manu-
facturers of proprietary medicines to declare the
amount of poison in their preparations, and insist
that they shall bear the responsibility arising from
any inaccurate or misleading statement on the
point; or they may take a short cut to the solution
of the difficulty by refusing to sell retail any such
preparation containing poison."

The "short cut" would certainly seem to be the
most honest and generally satisfactory way out of
the difficulty, for conscientious and law-abiding
citizens. And the suggestion of a further difficulty—
 arising in cases where manufacturers have declared
that they had ceased to add poisonous ingredients,
and after a certain interval reverted to their
former custom—only emphasises the desirability of
total abstinence, on the part of grocers, from engaging
in business for which they are not in any degree
qualified. The position is indeed "a most unsatis-
factory one, and can hardly be left as it is." Even
it—as stated on what may be regarded as doubtful
grounds—"manufacturers of proprietary prepara-
tions are fully alive to the fact that the grocer
is a far better distributing medium for their goods
than the chemist," that does not render the Phar-
macy Act invalid, or justify infractions of the law.
The numerous arguments adduced by our con-
temporary in support of its case are either irrele-
vant or incorrect. In the first category must be
placed the reasertion of the supposed agreement
between the manufacturers of proprietary medicines
and the promoters of the Pharmacy Act in 1888, and
in the second the assertion that the Pharmaceutical
Society has acted upon such a bargain for twenty-
four years. It is wrong, again, to say that the
Inland Revenue authorities issue "patent" medici-
ne licences, the correct style being "stamped
medicine licences," as anyone possessing a licence
can readily ascertain on the most cursory in-
pection. Further, it is quite beside the question
to state that the trade and the public have under-
stood the term "patent medicines" to include medici-
ines which are not patented, since popular error
affords no justification for illegality.
It is merely playing with words to assert that the judges "took a somewhat sentiment view of the matter, and considered that by so doing they were safeguarding the public health." It is pleasing ignorance that does not exist to ask "how that can be done by giving a certain class of traders a monopoly in the distribution of sealed goods, the ingredients of which they do not know?" Such a plea of impracticability serves only to show that there is good ground for the claim now being made in the medical papers that the composition of all proprietary medicines should be disclosed on the labels of each package, and that the neglect of this condition should subject the vendors to a penalty.

The key to the whole situation is for grocers and others to be content to obey the law, which insists that scheduled poisons must only be sold under certain prescribed conditions, by duly registered persons. If individuals who do not possess the necessary legal qualification desire to make the sale of medicines a part of their business, they will do well to act upon the advice of their former mentor, the Patent Medicines Journal, no less than that of the Grocer, which now warns them to be careful "in all their purchases of proprietary medicines to obtain an assurance from the manufacturers that they are such as can be legally sold by unregistered persons." Better still, perhaps, they might, with very great advantage to themselves and the public, altogether abstain from ignorantly trafficking in medicines of any sort or description.

SCHOOL OF PHARMACY.

The School of Pharmacy of the Pharmaceutical Society will be opened for the fifty-third session on Wednesday, October 3. The distribution of prizes to the successful students of last session, by the President—Mr. Michael Cartwright, will take place on the afternoon of that day, at the Society's House, Bloomsbury Square. The chair will be taken at three o'clock precisely, and the inaugural sessional address will be delivered by Mr. Walter Hilla, the present head of the historic firm of John Bell and Co., and Member of Council of the Pharmaceutical Society. The Dean of the School, Professor Reynolds Green, Sc.D., M.A., will be in attendance on October 3, between the hours of 10 a.m. and 1 p.m., to enter the names of students, issue cards of admission, and furnish information relating to the courses of study. The Professors and Lecturers will also be present, prepared to advise students with reference to their special subjects. Applications for admission to the School and for further information should be addressed to the School Secretary, Mr. F. W. Short, 80, Bloomsbury Square, W.C.

The Sheffield School of Pharmacy, conducted by the local pharmaceutical association, will commence its tenth session on Thursday, October 11, when an introductory address will be given by Mr. C. B. Allen, of Kilburn, Member of Council of the Pharmaceutical Society. By means of this school, it will be remembered, the Sheffield Pharmaceutical and Chemical Society has endeavoured to impart to students a sound foundation of scientific and technical knowledge, during the period of apprenticeship. Though, naturally, very great difficulties have been encountered from time to time, the good record has now remained unbroken during nine consecutive years, and the number of young pharmacists who have thus received assistance and encouragement has been surprisingly great.

PHARMACY FAIR AT BOSTON.

According to the Boston Journal, preliminary arrangements have been perfected for the American Pharmacy Fair, which is to be held in Mechanics Hall, Boston, May, 1895. This exposition will be the first of its kind ever attempted in America, and is projected by Mr. Benjamin Johnson, publisher of the New England Druggist, who is supported by some of the leading American pharmacists. It is expected that the fair will be opened on or about May 1, 1895, and that it will remain open for three weeks at least. Assurances have already been received from various quarters of sufficiently large and varied exhibits to make the exhibition a success. Part of the exhibits will illustrate the methods of chemical teaching, and there will be an exhibit of the constituents of foods and medicines, each important constituent of any article being shown as a separate preparation, in the average natural proportion in which it exists in it. It is also expected that the great exhibit shown by Harvard University at the World's Fair last year will be secured for this fair, containing as it did samples of over 200 new compounds, as well as fifty old substances specially investigated in the chemical laboratory. The case attracted widespread attention, containing, as it did, many compounds rare enough to be considered as chemical curiosities. There will also be exhibits of the thousand and one things which may be found in any well-appointed drug store.

THE HEMP DRUGS INQUIRY.

It is stated that the general conclusion of the Hemp Drugs Commission as stated in the report is that the total prohibition of the cultivation of Indian hemp is neither necessary or expedient, when allowance is made for the ascertained effects and social religious feeling, and the possibility of present consumers being driven to more dangerous drugs. The policy advocated is one of control, restricting excessive and restraining moderate use. The means to be adopted involve adequate taxation, prohibition of unlicensed cultivation, and limitation of shops. A Government monopoly is not recommended; import and export duties are undesirable; and a direct duty is considered best. With little interference from Government it is thought a direct duty might be made to act as a check on consumption. Practical recommendations are given in detail by the Commission.

EDINBURGH PHARMACY ATHLETIC CLUB.

The third annual picnic of this club took place on Monday last. Favoured with splendid weather, the party, to the number of about thirty, drove out fourteen miles to Crichton Castle, where an enjoyable day was spent, Edinburgh being reached about 10.30 p.m., everybody having thoroughly enjoyed the outing.
British Pharmaceutical Conference.

PAPERS TAKEN AS READ AT THE OXFORD MEETING.

NOTE ON TINCTURA EROTÉA AMMONIATA.

BY J. T. HORNBLOWER.

The subject of this note was suggested to the writer a short time back by a question being put to him as to why a sample of tinct. ergot. ammon. remained clear on adding it to water, and another become cloudy. The question was therefore — Should the tincture remain clear on adding it to water (3f to 2 f. oss.) or not?

On looking at the subject in a cursory manner, I think one might be pardoned for saying the tincture should become cloudy, or even milky, seeing that the menstruum is sp. ammon. aromat.; and, indeed, if I had been asked if a tincture would do so, instead of being told it did not do so, I should have said yes. Accordingly, I added some to distilled water in the proportion of 3f to 2 f. oss., and observed that the tincture became clear mixture. When came the question — What was the reason?

This, I surmised, was owing to the large amount of fixed oil which ergot contains. It might be that this oil had the power of removing the essential oils from the sp. ammon. aromat., and to a great extent this proved to be right, but not quite so. The following experiments were then done to try and find the reason —

Ten ounces of ergot were exhausted of oil with 720 ether, the oil resulting being some 3f oss.

1. Half ounce of this oil was shaken up with 4f. oss. sp. ammon. aromat. (these quantities were used because 4 f. oil would be about equal to 14 f. oss. ergot, which would equal 3 f. tincture, which would require 4f oss. sp. ammon. aromat. to produce it if made strictly B.P.C.). After standing, etc., and a portion filtered off, 3f of this spirit was added to 2 f. oss. distilled water, the result being a perfectly clear mixture.

2. Half ounce of the same oil was shaken up with 4f. oss. sp. aromat. sine ammonia (this being a spirit of the same alcoholic strength as sp. ammon. aromat., and containing the essential oils, but no amonam.) On filtering off a little of this spirit, and adding it to water, a turbidity or cloudiness took place, but this was approaching the milkiness formed on adding an equal quantity of sp. ammon. aromat. to water. The partial removal of the essential oils is, of course, due to the difference in solubility of these oils in the fixed oil and "sp. aromat."

3. To the mixture of this latter fixed oil and sp. aromat. sine ammonia, the proper amount of ammonica, caustic and carbonate, was added to form sp. ammon. aromat., and the mixture again well shaken for some time, and then a portion filtered off. This, on adding to water as before, remained quite clear. The addition of the ammonica (caustic) had evidently brought the change, by the formation with the fixed oil of a small amount of soap, which had doubtless the effect of keeping in solution, when added to water, that portion of the essential oils which the fixed oil had not removed.

4. One ounce of ergot was then taken, made into a No. 30 powder, and then into tincture with sp. aromat. sine ammonia. On adding this tincture to water as before, the same amount of cloudiness took place as when the "sp. aromat." treated with oil as in No. 2 experiment, was used, thus showing that the oil either distributed through the ergot, or treated separately had exactly the same effect on the "sp. aromat." that being partially removing the essential oils from it.

5. The equivalent of 1 oz. ergot exhausted of its oil was now taken and made into tincture, B.P.C. This should have made a milky mixture with water if the fixed oil had been thoroughly removed from the ergot, as we know there it could neither act on the essential oils in the spirit nor the ammonia act on it. On diluting the tincture with water a thorough cloudiness took place, though not so much as a proportionate amount of sp. ammon. aromat. would have caused with water. The fixed oil was evidently not thoroughly removed from the ergot, more cloudiness must have been produced, for on again treating a portion of this ergot with more ether and making another tincture this, on adding to water, became more as expected. Of course, there was not sufficient fixed oil left in the ergot to effect a solvent action on the essential oils of the sp. ammon. aromat., but there evidently was sufficient to form soap enough to make the tincture remain more clear than it otherwise would have done on adding it to water.

6. To 2 f. oss. distilled water add 5 minims of a solution of hard soap (grs. 40 in 1 oz. spirit), and then add 3f sp. ammon. aromat. The mixture will become nearly clear, and on adding another 5 minims of soap solution, quite so. The presence of this amount of soap evidently keeping the essential oils in solution.

The reason therefore, I think, why tr. ergot. ammon. remains clear on adding it to water is that the fixed oil of the ergot, and the soap formed from it by the ammonia, respectively remove part, and prevent the remainder of the essential oils from being thrown from solution; this, however, can only apply when the whole of the tincture has been in contact with the ergot, as in percolation—for if made by macerations, and any deficiency in quantity of finished tincture made up by adding sp. ammon. aromat., a clodliness would be produced, dependent on the amount added.

A SOAP BASIS FOR LINIMENT.

BY E. W. LUCAS, F.C.S.

The many advantages that the basis of liniment of potassium iodide has over the rest of the Pharmacopoeia liniments induced the suggestion as to whether it would be practicable to adopt a similar basis to other preparations of the same class. It is exceedingly probable that such liniments would be more readily and more easily applied, and at the same time the danger of mistake for medicines for internal use would be minimised. The author, therefore, proposes the adoption of a soap basis, from which all of the liniments now dealt with could be readily prepared.

Basis Saponis.

Take of—

Soft soap .................. 1 ounce.
Curd soap .................. 5 ounces.
Glycerin .................. 2 fluid ounces.
Distilled water .......... a sufficiency.

Reduce the curd soap to fine shreds, and dissolve it with the soft soap in 16 ounces of water, by the aid of gentle heat. Add the glycerin and sufficient distilled water to make the strained product weigh 1 lb. 10 oss. Pour into a suitable vessel and allow to solidify.

Linimentum Aconiti.

Take of—

Alcoholic extract* of aconite . . 14 ounces.
Distilled water ................. 4 fluid ounces.
Soap basis .................. 12 ounces.

Liquefy the soap basis on a water-bath, add the distilled water, and dissolve the extract of aconite in the mixture, and as soon as it begins to cool, pour into

* Prepared in the same way as ext. belladon. alcoholic.
a large mortar, and stir briskly until a smooth paste is
produced.

**Linamentum Belladonna.**

Take of—
- **Extract of belladonna** (alcoholico) 1½ ounces.
- **Distilled water** 4 fluid ounces.
- **Soap basis** 12 ounces.

Liquefy the soap basis on a water-bath, add the
distilled water, and dissolve the extract of belladonna
in the mixture, and as soon as it begins to cool pour
into a large mortar, and stir briskly until a smooth
paste is produced.

**Linamentum Camphora Composition.**

Take of—
- **Camphor** 2 ounces.
- **Oil of lavender** 1 fluid dram.
- **Strong solution of ammonia** 5 fluid ounces.
- **Rectified spirit** 2 "
- **Soap basis** 14 ounces.

Dissolve camphor and the oil of lavender in the
spirit, and add the solution by degrees to the previously
melted but cool basis, stirring briskly after each addi-
tion. When nearly cold, add the solution of ammonia,
and continue stirring until a smooth, creamy paste is
produced.

**Linamentum Iodi.**

Take of—
- **Iodine**
- **Iodide of potassium** of each 1 ounce.
- **Rectified spirit** of each 1 fluid ounce.
- **Soap basis** 10 ounces.

Dissolve the iodide of potassium in the spirit and
water, and add the mixture by degrees to the previously
liquefied soap basis. As soon as it begins to
thicken, pour into a large mortar, and stir briskly
until a smooth paste is produced.

This is about one half the strength of the pharma-
copoeia liniment, but it will probably be found quite
energetic enough, owing to its being more rapidly
absorbed. The title of the present liniment it is pro-
sposed should be changed to "pigmentum iodi," under
which name it might be retained.

**Linamentum Opii.**

Take of—
- **Extract of opium** 2 drachms.
- **Distilled water** 2 fluid ounces.
- **Soap basis** 10 ounces.

Dissolve the extract of opium in the water, add the
previously liquefied soap basis, and as soon as it begins to
thicken, pour into a large mortar, and stir briskly
until a smooth paste is produced.

**Linamentum Potassii Iodidi cum Sapone.**

Take of—
- **Iodide of potassium** 14 ounces.
- **Oil of lemon** 1 fluid dram.
- **Distilled water** 2 fluid ounces.
- **Soap basis** 10 ounces.

Dissolve the iodide of potassium in the water and
add it to the previously liquefied basis. As soon as it
begins to thicken, add the oil of lemon, and pour the
mixture into a large mortar, and stir briskly until a
smooth, creamy paste is produced.

**Linamentum Saponis.**

Take of—
- **Camphor**
- **Rectified spirit** of each 1 ounce.
- **Oil of rosemary** 2 fluid ounces.
- **Soap basis** 18 ounces.

Dissolve the camphor in the oil of rosemary and
spirit, and add by degrees to the liquefied but nearly
cold basis, stirring constantly until a smooth, creamy
paste is produced.

**Linimentum Terebinthinae.**

Take of—
- **Soft soap**
- **Castile soap in shavings** of each 1 ounce.
- **Distilled water** 2 fluid ounces.
- **Camphor** 1 ounce.
- **Oil of turpentine** 16 fluid ounces.

Place the oil of turpentine in a narrow-mouthed
bottle with the soaps and the camphor, and stand in a
vessel of hot water, agitating occasionally until solu-
tion has been effected. Add the water all at once
and shake vigorously until a creamy white liniment is
produced.

**Tincture of Iodine and its Analysis.**

**By J. F. Liverseberg, Ph. Q.C., Ph. G.**

1. Composition.—The British Pharmacopoeia orders
half an ounce each of iodine and iodide of potassium
to be dissolved in one pint of rectified spirit, which is
required to contain 84 per cent. of absolute alcohol,
and to have a specific gravity of .833. The percentage
by weight of the ingredients of the tincture can there-
fore be calculated. As it is practically inconvenient to
weigh the portions of tincture for analysis, the com-
position in grammes per 100 C.c. is also required. If
the Pharmacopoeia gave the volume of the product or
its specific gravity, these values could also be calcu-
lated, but as it does not, experiment is required. I
found that when 23 grammes each of iodine and
iodide of potassium are dissolved in 100 C.c. of recti-
ified spirit the volume of the product is 101.2 C.c.

The theoretical composition of the tincture is there-
fore:—

<table>

<td><strong>87.75</strong></td>
</tr>
</tbody>
</table>

2. Specific Gravity.—This is conveniently taken
with the Westphal balance, or a stopped specific
gravity bottle with a mark on the neck. If the
temperature is about 60° F., the specific gravity thus
found may be corrected by the addition or subtraction of
.0005 for each 1° F. above or below the normal tem-
perature.

I have stated that 100 C.c. of the tincture should
weigh 87.75 grammes; the specific gravity, therefore,
should be .8775. The only published statement I
know gives the theoretical value as .861 (Findslay,
Pharm. Journ., [3], xix, 472), but does not say how
this erroneous value is found.

The specific gravity bottle was calibrated to hold
50 grammes of water at 60° F. May I here express
the hope that the new Pharmacopoeia will supplement
the somewhat indefinite statement (page xix) "Specific
gravities are to be taken at 60° " with the words, "and
compared with distilled water at the same tempera-
ture."

3. Iodine.—This is readily determined by titrating
5 C.c. with sodium thiosulphate and starch. The
reaction is so delicate that I prefer a solution weaker
than that of the British Pharmacopoeia, viz., one con-
taining 13.7 grammes Na,S,O₃.5H₂O per litre; each C.c.
of this is equivalent to 0.01 iodine. If found that
commercial "hypo" is dissolved in hot water, filtered
and cooled, the small crystals when dry are pure, and
may be directly weighed out for the solution without
the necessity of standardisation with iodine. A solu-

* As my pipettes are calibrated to contain a gramme of water for each C.c. marked on them, measured at 60° F.,
I here use the term "C.c." in that sense.
tion of iodine in rectified spirit was calculated to contain 4.96 grammes per 100 C.C., and 4.93 was twice found.

4. Potassium Iodide.—I thought that by evaporating the tincture to dryness on the water-bath all the iodine would be volatilised, and that the potassium iodide might be weighed; though most of the iodine is lost, heating to 150° C. does not remove it all, and at a higher temperature part of the iodide of potassium is volatilised.

If 5 c.c. of tincture is evaporated to dryness in a dish with a flat bottom, and small quantities of absolute alcohol are repeatedly evaporated on the residue, all the iodine is volatilised; and, after drying in the water-oven the residue may be weighed. As a check the salt is dissolved in water and titrated with volumetric silver solution, using potassium chromate as an indicator.

A solution of potassium iodide in rectified spirit was calculated to contain 4.92 grammes per 100 C.C., and 4.92 was twice found by weighing, while titration gave 4.91 and 4.87. The volatilisation of iodine was also tested by taking a measured quantity of a rectified spirit solution of potassium iodide, adding a solution of iodine in rectified spirit, evaporating to dryness, treating with distillation water, and weighing and titrating. Another equal quantity was evaporated to dryness, without addition of iodine, weighed, and titrated as a check. The results were: —

Iodide only ....1115 KI by weighing..1100 KI by tiration.
Iodide and iodine.1135 KI by weighing..1115 KI by tiration.

In making the aqueous solution of the residue I was puzzled by the presence of a pink colour, very similar to ferric sulpho-aniline. Iron and iodine were both tested with negative results; but as the colour is not obtained if porcelain dishes are used, and as the colour is fainter if no iodide is present, when the evaporation is much more rapid, and the iodine a shorter time in contact with the platinum, it appears probable that the pink colour is due to a minute quantity of iodide of platinum.

Neither weighing nor titration is absolutely accurate, as any other salt present is weighed as potassium iodide, and any acid chloride is present the results of titration are too high; but for practical purposes, either answer very well. I never find one-tenth per cent. difference between the two results. The figures given below are the means of the two methods.

I may point out the alterations which have taken place in the amount of potassium iodide ordered by the pharmacopoeias. London, 1 oz.; British, 1864, 1 oz.; 1885, 1 oz. to each pint of spirit. The foreign pharmacopoeias omit it altogether.

6. Spirit. (A) Direct Determination.—Allen (‘Commercial Organic Analysis,’ 1, 112) writes: “Mere distillation is sufficient to separate the alcohol . . . . in tincture of iodine, etc. . . . . if they are not treated with soda in slight excess.” I took 16 C.C. of a tincture of iodine, specific gravity 8792, calculated to contain 69.07 grammes absolute alcohol per 100 C.C., made slightly alkaline with soda and diluted to about 60 C.C., when a reaction took place that might have been due to the principal, iodine. The contents of the liquid on heating became clear, but the distillate contained a notable amount of iodiform, rendering its specific gravity too high, and the quantity of absolute alcohol calculated therefrom too low, viz.: 65.65 grammes per 100 C.C. Experiment showed that the reaction took place, whatever was the order of mixing.

I then decolourised 15 C.C. of the same tincture with sodium thiosulphate, added a few drops of soda, diluted to 60 C.C., distilled about 45 C.C., diluted to 50 C.C., weighed and calculated by the formula:—

\[
\text{Grammes absolute alcohol} = \frac{\text{Per cent. absolute alcohol}}{\text{Weight of distillate per 100 C.C.}} \times \frac{1}{\text{distillate}}
\]

C.C. tincture taken.

The result was 69.67 against the theoretical 69.07; the error may be due to sulphur coming at the end of the process, and making the distillate slightly turbid.

(B) Indirect Determination.—If iodine or iodide of potassium is dissolved in spirit, the increase in its specific gravity is proportional to the weight dissolved; conversely, if the specific gravity of the tincture, the amount of iodine and potassium iodide present, and their influence on the specific gravity be known, the specific gravity of the spirit used for making the tincture may be calculated.

To determine the effect of iodine, 50 C.C. of rectified spirit was put in a stoppered specific gravity bottle with nine marks on the neck and weighed, from this the specific gravity of the spirit was found. About 2.5 grammes of iodine was added, the increase in weight being the exact amount. When the iodine was dissolved, the volume was estimated by means of the marks on the neck, and this divided into the total weight gave the specific gravity of the solution. A second value was obtained by assuming the volume was exactly at a mark when the temperature was taken, and the volume at 60° F. calculated by means of the co-efficient of expansion. I thus found that one gramme iodine in 100 C.C. of spirit increased the original specific gravity by 0.008, and similarly one gramme potassium iodide increased the specific gravity by 0.007. As there is so little difference in these figures, and as the iodine and the iodide ought to be present in equal quantities, no appreciable error will be introduced if the sum of the iodine and the iodide is multiplied by the mean of the two results, viz., 0.008. Therefore:—

\[
\text{Sp. gr. of the spirit used for making the tincture} = \frac{\text{Sp. gr. of the iodine}}{1 + \text{KI in grammes per 100 C.C.}}
\]

For example, a tincture of iodine had a specific gravity 0.787, and contained 230 grammes iodine and 2.84 grammes potassium iodide per 100 C.C. Then the specific gravity of the spirit multiplied by the tincture = 878 - [2.30 + 2.34 (0.008)] = 841, while the specific gravity of the spirit actually used was 842.

(C) Approximate Determination.—Into a 500 grain graduated cylinder were successively put 50 fluid grains each of tincture and water, and 400 fluid grains of methylated ether (717), and the mixture shaken. After standing the aqueous deposit measured 65 fluid grains. Reference to my table (‘Year-Book of Pharmacy,’ 1891, p. 256) showed this indicated 75.6 per cent. of absolute alcohol, while 78.5 per cent. was calculated to be present.

6. Analysis of Samples.—Table I contains those samples which vary less than 10 per cent. from the theoretical standard, and have been probably more or less carefully prepared, according to the Pharmacopoeia.

Two samples were bought from unqualified vendors.

Table II. contains carelessly made or adulterated tinctures; two of these (Nos. 19 and 20) were bought from unqualified sellers, the remainder (in both tables) from retail chemists.

I also give the averages, which agree remarkably closely with the theory. No. 25 is omitted from the average of the specific gravities, because of its wide divergence from any of the others.

### The Calibration of Pipettes

BY J. F. LIVERBEEGE, F.I.C.

It is, I believe, a not uncommon practice to accept pipettes as accurate without calibration, and as I have never seen any figures given of their actual contents as sold, the following results may be of interest.

Before calibration it is advisable to ascertain that the pipettes are free from grease; if present, it may be removed by half-filling the pipette with soda solution, and carefully heating the bulb with a spirit lamp, then thoroughly washing.

To obtain concordant results, it is necessary to adopt a definite procedure in employing the pipette, for if it be allowed to drain one time, blown out another, and only allowed to run out a third time, the amounts of liquid delivered will not be the same.

The pipettes and a beaker of distilled water are put near the balance and allowed to attain the temperature of the room. A flask is placed, the temperature of the water noted, the pipette filled with water, the outside wiped, adjusted to the mark, allowed to run out into the flask, drained five seconds, the surface of the liquid touched with the pipette, and the flask of water weighed.

Proceeding in this way two determinations generally agree (irrespective of the sizes of the pipettes) to within a few milligrams; in fact, in 60 per cent. of a number of determinations the difference was less than five milligrams.

If the temperature of the water is not 15° C., it is corrected to that temperature by the following table, which is calculated from data given by Cassamajor (Chemical News, xxxiv., 160 and 170).

</tbody>
</table>

As the British Pharmacopoeia requires a grain measure to be the volume of one grain of water measured at 16° C., and as the fluid ounce is the volume of 437.5 grains of water at 16° C., it will be seen that a fluid ounce is not exactly 437.5 grain measures; but a trifle (07 grain) more. This difference will not therefore account for the errors of the following British pipettes:

With regard to metric pipettes, there is a certain amount of doubt as to the temperature at which a pipette is expected to deliver a gramme for each cubic centimetre marked on it. Thorpe advocates 4° C. (the strict C.C.), Dittmar 15° C., Sutton "16° C. or 60° F."

The following are the mean results of the examination of a series of metric pipettes:—The 10 (9), 3, 2, and 1 C.C. pipettes had the bulb at the bottom, the 5 C.C. had no bulb, and all the rest had the bulb in the middle of the stem.

The variation in the direction (+ or -) and percentage of error (0 to 8%) shows that there is no uniform system among the makers of pipettes, or that they are sold at too low a price to be consistent.

I have taken one gramme measured at 15° C. as a standard cubic centimetre, as it is a convenient temperature for calibration, and as it is the standard temperature for volumetric measurements. If the term cubic centimetre, as thus applied, be objected to as not strictly accurate, the expression "fluid gramme" may be used as suggested by Dittmar.

Fresenius considers an error of one tenth per cent. of the contents allowable, and the errors of one third of them (those marked * ) do not exceed this amount. Bearing in mind that the "fluid gramme" exceeds the cubic centimetre by one thousandth part, it will be
seen that about the same proportion is condemned if
the true cubic centimetre is taken as the standard.

</tbody>
</table>

In two cases the error exceeds 1 per cent., and in
three more the error exceeds 2 per cent. This is hardly
satisfactory, and the pipettes require correction for
practical use.

An approximate correction may be made by the
formula \( \lambda = \frac{r}{\pi} \) where \( \lambda \) = distance in Cm. of correct
mark from erroneous one. \( C = \text{error in C.c.} \times 3-8146 \)
and \( r = \frac{1}{2} \) half the internal diameter of the stem in
Cm., or by adding water from a burette to the pipette
when full to the mark. After the approximate correction
they were calibrated, and a further alteration
made if required. The following are the results
after correction:—

**Extraction of Indian Hemp.**

**BY DAVID HOOBER.**

The chief medicinal preparation of Indian hemp is
that part of the cultivated female plant of *Cannabis sativa*
known as ganja, and the most important pharma-
cutical preparation of ganja is the spirituous extract.
Dr. W. B. O'Shaughnessy was the first to draw
attention to the use of this plant in European medi-
cine, and published a pamphlet on the subject in Cal-
cutta in the year 1838. The history and therapeutics
of ganja were very fully treated in the "Bengal Dis-
pensatory" of 1842, pp. 579-601. Indian hemp and
its preparations were introduced into the British
Pharmacopoeia of 1864 and 1867; before this, as
far as I can ascertain, they were in the Dublin
Pharmacopoeia. Indian hemp, with its extract
and tincture, was one of the few drugs that were
allowed to pass into the Pharmacopoeia of 1885 with-
out any criticism, an indication, probable, that the
values of English and Indian extracts, has been on the
White List of the Conference, but this year it has been
omitted from the list of topics suggested for investi-
gation. Before this drug takes a lower position in
pharmacy than it is present occasion, I would venture
to give my experience of the extracts of Indian hemp
obtained from different sources, and compare them
with extracts of English manufacture. My recent
position of analyst to the Indian Hemp Drugs Com-
mッション has given me unprecedented opportunities
of learning about the composition of Indian hemp.
My remarks will have particular reference to the pharma-
copotal extract, a preparation which contains the
active principle of hemp. A summary of nearly fifty
literary references to the chemistry of the drug, and
a discussion on the active principle, based on some
experiments now being conducted, will be left for a
future occasion.

**Preparation of the Extract.**—Commercial samples of
ganja contain from 5 to 40 per cent. of seeds, or,
properly speaking, fruits, and as the seeds yield 25 per
cent. of oil largely soluble in alcohol, a spirituous
extract would often contain a considerable quantity of
fixed oil. In breaking up a sample of ganja the seeds
that fall out should be rejected altogether. In all
my analyses I removed as much seed as possible
before the sample was reduced to coarse powder, and
in this way resinous extracts of greater purity could
be prepared.

Rectified spirit answered every purpose in extracting
the different samples of ganja. In some cases where
the resin was high, a stronger spirit was used as a
solvent, but this did not affect the solution of a larger
quantity of resin. Rectified spirit dissolved from the
drug some water-soluble matters in addition to the
resin, while absolute alcohol dissolved very little
besides the resins. The following experiments will
show the difference in the solvent power of spirit
of different gravities on samples of ganja:—

**Amount of Extract in Ganja Samples.**—Like all other
drugs, the amount of active principle, which is here
gauged by the resin contents, varies greatly in different
samples. Dr. O'Shaughnessy, of Calcutta, obtained
20 parts of resinous extract from 100 parts of ganja.
The ganja used was no doubt that cultivated at
Nagpore in Raphail District, Bengal, and known all
over the north of India for its uniform richness in
resin and its active properties. Mr. Savory (Pharm.
Journ., August, 1843) seems to be the first English
pharmacist who published his experience in making
an extract of Indian hemp. By a very exhaustive pro-
duce, consisting in macerating the ganja in spirit
for a week, and then percolating with hot spirit, he obtained
12 ounces of extract from 4 pounds, or 18-2 per cent.
Indian hemp is official in the United States, and the
process for preparing the extract is very similar to
that of the B.P. F. J. Lammer (Am. Journ. Pharm.,
November, 1880), by following the directions of the
U.S.P., obtained 16-6 per cent. of finished extract.

In the following table are recorded some of the results
of my examination of selected samples of ganja from
various parts of India. The first column gives
the percentage of rectified spirit extract evaporated
to absolute dryness and calculated on the air-dried
sample of ganja. The percentages of extract range from 1 to 5 in the Bijapur specimen to 30 in that from the Kistna district of Madras. The new, unripe, and young portions are all very high, and are, in fact, different preparations of the same crop of hemp. The first kind is the "chur" of ganja, or small matted pieces separated as much as possible from the stalks. The second kind is called "slender flat twig," or ganja on small stalks. The third kind is "large flat twig," or ganja on large stalks. The fourth kind is known as "round ganja," prepared by rolling the fresh flowering and fruiting tops by the drying and weighing the resinous residue left in the capsules. In the second column of the following table will be found the weights of the washed spirituous extracts expressed in percentages on the air-dried ganja. The third column shows the results of control estimations, which consisted in extracting the ganja directly with ether, then with ether, separating the resin from the spirit extract, and mixing together the ether and spirit solutions after drying and weighing. The chief constituent of the extract is a neutral resin of a brown colour and tough consistency, soluble in petroleum ether, benzol, ether, carbon bisulphide, and amyl and ethyl alcohol, insoluble in alkalies, and leaving no ash when incinerated. A small quantity of resin acid, about 1 per cent., is present in all the samples. This has been found by Dr. D. Prain, of Calcutta, to be physiologically inactive. Oil, fat, wax, and chlorophyll also enter into the composition of the spirituous extracts insoluble in water. The water-soluble substances removed from the extract are chemically interesting, although not yet proved to be medicinally active. An alkali is present in nearly all the fresh samples of ganja, it occurs only in traces in older specimens, and is altogether absent in extracts that have been kept for some years. Ammonia is often associated with this alkali in fresh hemp, it exists in solutions in older samples and is usually found only in traces in old extracts. The alkali and ammonia are combined in the plant juices with one or more organic acids. One of these acids has the properties of citric acid, and another gives a yellow colour with lead acetate solution, and resembles an amorphous organic acid often found in plants. A substance is present in the extract which gives a purplish-black colour with ferric chloride, rapidly turning into a brown precipitate, and the precipitate dissolves in soda liquor with a red colour. Sugar has not to my knowledge been detected before in hemp drugs, but it is present in all the Madras ganja examined, and in the leaves only from cultivated and wild plants from other districts. Traces of sugar were found in some of the Bengal and Bombay ganjas, nearly 5 per cent., was present in the sample from Ghasipur in the North-Western Province, and the Madras samples contained from 6 to 7 per cent. A glance at the fourth column in the table will show how the sugar increases the proportion of spirit extract soluble in water in these samples. The sugar was amorphous, and easily reduced Feulgen's solution.

Examinations of Commercial Extracts.—I have obtained three samples of Ext. cannabinum made in England, and have examined them with the object of comparing them with the above extracts made from Indian material.

1. Sap green colour, hard consistence, homogeneous under the microscope.
2. Sap green colour with brown specks observable under the microscope, rather soft consistence.
3. Dull green colour and soft consistence. Microscope revealed the presence of brown specks, hairs, glands, cubical crystals (chloride of potassium), and prisms (citr.)

1 4.20 1.22 6.25
2 6.36 2.21 9.58
3 12.14 4.78 19.35

The first sample was a portion of very old stock of extract; the second sample was also very ancient, some brown juice and mouldy particles were on the sides of the vessel in which it was kept; the third sample was said to be from a fresh consignment. From the microscopic and chemical examinations, we should consider the first sample to be the best, as
it yields the largest proportion of pure resins, and the third sample the worst. It would seem that the ash bears a certain ratio to the water-soluble substances, and is traceable to the saline constituents of the plant. Manganese is present in the ash of Indian hemp grown in different localities, and was found in the ash of the extracts. On igniting the aqueous extract obtained from the third sample, deslagration ensued, owing to the potassium nitrate present. Nitre has been found in Indian hemp by Messrs. T. and H. Smith (Pharm. Journ., April 18, 1874). Its presence in the spirit of wine was accounted for by the supposition that other bodies were present to aid its solution.

After observing the dull olive-green colour of the extracts obtained from a large number of ganjas, I could not help noticing the very bright green tint of the commercial extracts when spread out on glass dishes, and I was not surprised to find copper in each sample. When the extracts were burnt in a platinum dish the copper present communicated a green colour to the flame, and the ash of each extract when dissolved in nitric acid and the solution saturated with ammonia resulted in a deep blue solution. The presence of this metal in manufactured extracts has been pointed out by different chemists, and it has been shown by Dr. Squibb and Mr. H. Maclagan (Pharm. Journ., Oct. 18, 1884) that its commencement of the extract cannot be prevented when copper evaporating pans are used. In face of these experiments, I was amazed to find that in a paper published in the Pharm. Zeitung (Chem. and Drug., June 9, 1894, p. 802) a firm of manufacturing pharmacists has tried to attribute the copper found in extracts to its presence in the drugs themselves. I have examined the ash of bhang and ganja and have not discovered copper, but the amount of this metal in the extracts is decidedly higher than that shown in the paper (24 milligrammes per kilo).

Ganjas always lose their strength when kept for some time, and many dealers in India obtain new supplies annually, and always consider the drug worthless after being kept three years. This is a matter worthy of consideration in England with reference to the extract, and the failure of the action of the drug (thermal) to the decomposition of its active principle is probably the cause of its downfall in medical estimation.

Patent Office Business.

Patents for Medicinal Preparations.

Complete Specifications Accepted.
No. 9726.—August 11, 1894.—James Taylor and John Taylor, both of 4, Bank Street, Alexandria, N.B. A salve for sores, composed approximately as follows:—aqua fortis, 3 ounces; quicksilver, 1 ounce; lard, 18 ounces; carbolic oil, 18 ounces.
No. 12,432.—July 28, 1894.—Patrick Richard Reid, of 97, Upper Georges Street, Kingston, Ireland. A new medicinal compound for the treatment and cure of whooping cough, composed approximately as follows:—sulphate of quinine, 18 grains; hydrobromic acid, 30 drops; hydriodate of potash, 18 grains; spirit of chloroform, 3 drachms; simple syrup, 3 ounces; liquor of red poppies, 2 scruples; pure carbonic acid gas, 6 to 6 gr. in each dose.
No. 18,446.—August 11, 1894.—Oscar Troplowitz, of Lockstedter Weg 96, Hamburg-Elmsbuttell Germany. The production of siocative or drying ointments by emulsion of vegetable or animal fats or mineral oil with neutral or alkaline solutions of casein.

Parliamentary and Legal Proceedings.

Poisoning Cases and Inquests.

Poisoned by Carbolic Acid.

Dr. G. Danford Thomas held an inquest on September 13 on the body of Joseph Lomas, aged 3 years, the son of a cabdriver, of 11, Ann Street, Clerkenwell, who died the previous Monday from the effects of carbolic acid poisoning. The poison had been obtained in the crude state from the Clerkenwell Vestry Hall for disinfecting purposes by a Mrs. Roberts, who lived in the same house. Some of it was subsequently placed in an unlabelled ginger-beer bottle, which was left on the landing. The little boy, who used to stay with his mother out of the room, took up the bottle and drank some of the contents. He died shortly afterwards. The coroner called attention to the indiscriminate sale of deadly poisons which still went on,
despite the petition of the Pharmaceutical Society to the Privy Council to include carbolic acid with other poisons in the schedule of the Poisons Act. The verdict was "Death from misadventure."—Morning.

POLICE PROCEEDINGS UNDER THE PHARMACY ACT, SECTION XVII.

PENALTY FOR NOT REGISTERING SALE OF POISON.

At the Over Petty Sessions on Monday, September 10, before Mr. R. Wilbraham, Mr. C. Threlfall, Captain W. Smart, and Mr. G. Braddick, Thomas Pickering, druggist and chemist, High Street, Over, was summoned for that on July 16 he did sell to Jane Finney, of Over, single woman, a certain poison (strychnine) within the meaning of the Pharmacy Act, 1868, and unlawfully did not before delivering the poison make or cause to be made an entry in a book kept for that purpose, stating the date of the sale, the name and address of the purchaser, the name and quantity of the article sold, and the purpose for which it was stated by the purchaser to be required, with the signature of Jane Finney thereto affixed.

Defendant Gunn stated that on Monday, July 16, he called at Mr. Pickering's, and asked him what he had sold to Jane Finney. He said "A penn'worth of turpentine." Witness asked, "Nothing else?" and he replied "No." He asked him if he had sold her any pills, and he replied that he had not. On the 17th he (witness) again called, and defendant still maintained he had sold her nothing but the turpentine, and produced his register, in which no entry had been made. On Wednesday, the 18th, defendant called at the police station, and said he wanted to see witness. He then said, "I have sold Jane Finney one packet of vermin powder, and I did not make an entry in my register of it." Jane Finney purchased this on the Monday, between five and six o'clock. The packet contained strychnine. Witness purchased a packet from Mr. Pickering on Monday, August 3. He saw it was the same material as was supplied to Jane Finney. It was made up into a packet, and sold to him. The powder was not ready made up. Defendant told him there was strychnine in it, and entered it in the register. He paid 3d. for this packet. He purchased this for the information of the chief constable. The person to whom defendant supplied the powder had died. An inquest was held, and the verdict returned was to the effect that Jane Finney died from strychnine poisoning.

Mr. Pickering, in his statement to the bench, said that, so far as he knew, the law to supply no vermin powder without registering it was only just recently put into force. There were several well-known vermin-killers and dippers which contained a large quantity of arsenic, which he understood could be obtained with very little difficulty. He had never sold vermin powder to a stranger in his life, and what he had sold he sold with great caution. No one had suffered more—not even Finney's father—than he had done respecting this case. He regretted it very much. People who were not chemists could break this law, and sell compounds containing poison, yet he believed they were not proceeded against. He only supplied this powder to people he knew, people in whom he had the utmost confidence. He never for one moment dreamed this thing would happen.

Mr. Cooke said the law applied to everyone the same.

The Chairman said no doubt this little negligence on his part had caused defendant great distress, and he hoped now that he knew what the law was he would be more cautious. They really could not pass it over, and they would inflict a penalty of 20s. and costs.—Northwich Chronicle.

Notes and Queries.

FILTRATION OF MILK.

[774.] A simple method of purifying milk from the grosser particles that are apt to find their way into it is suggested by Dr. Seibert, who finds that filtration through a layer of absorbent cotton, 4 inch thick, shortens the time afterwards required for complete sterilisation, to a marked extent. The first table-spoonful of so of milk passing through the cotton is not used, as more bacilli pass through during the preliminary wetting than at any time afterwards. Subsequently, a quart of milk may be filtered in twelve to fifteen minutes. Children brought up on such filtered and afterwards sterilised milk are said to escape all gastro-intestinal disturbances (Archiv der Padi., and Am. Med.-Surgeon. Bulletin).

FOOD FOR INFANTS.

[775.] Dr. Oppenheim recommends the following process for preparing food for infants:—Mix a teaspoonful of flour and half a cupful of cold water, add twelve ounces of boiling water, and boil for ten minutes. Next add twelve ounces of cold water and half a teaspoonful of malt extract, allow to stand for fifteen minutes to let the diastase act upon the starch, boil again for fifteen minutes, then strain and add to an equal quantity of fresh milk (N. Y. Med. Journ., and Am. Med.-Surgeon. Bulletin).

CRYSTALLINE.

[776.] This preparation was described in the Journal some time ago (vol. iii., p. 442) as a kind of colloid in which methyl alcohol is employed as the solvent of the nitro-cellulose. A formula for elastic crystalline is given by M. Phillips, as follows:—crystalline, 20 Gm.; caustic alkali, 5 Gm.; Canada balsam, 10 Gm. An excellent white varnish for medicinal purposes is said to result on mixing the following:—crystalline, 30 Gm.; caustic alkali, 4 Gm.; zinc oxide, 8 Gm. (Rev. scient., and Bull. de Pharm. de Bordeaux).

PICTET GAS.

[777.] This is the name applied to a mixture of carbolic and sulphanuric anhydrides in the liquid state in equal parts by weight. It is supplied in metal cylinders and used for antiseptic and disinfecting purposes. In the Journal de pharmacie d'Amour, for September, are detailed the results of a number of experiments with the mixture upon bacteria, but it would appear that as good results can be obtained, much more economically, by the simple combustion of sulphur.

PHOSPHATED EMULSION OF COD LIVER OIL.

[778.] The following formula for this preparation is recommended by M. Marfan, the product being described as palatable and perfectly tolerated:—Tragacaanth, 5 Gm.; solution of calcium lacto-phosphate (5 per cent.), 150 Gm.; syrup of calcium lacto-phosphate (5 per cent.), 350 Gm.; cod liver oil, 500 Gm.; tincture of citron, 20 Gm. The tincture of citron of the French Codex is made from the fresh peel, one part to two of alcohol at 80° B. (Elyon Médicales and Moniteur).
Obituary.

Notice has been received of the death of the following:

On July 23, John James Fisher, Pharmaceutical Chemist, Carlisle. (Aged 68.) Mr. Fisher had been a member of the Pharmaceutical Society since 1869.

On September 6, William Taylor, Chemist and Druggist, Bridlington. (Aged 71.)

On September 7, Charles Jackson, Chemist and Druggist, Fulham. (Aged 67.)

On September 8, Henry William Hayden, Chemist and Druggist, Warrington. (Aged 67.)

On September 11, James MacFarlane, Chemist and Druggist, Glasgow. (Aged 49.)

On September 12, William Ashton, Pharmaceutical Chemist, Southport. (Aged 64.)

On September 14, William Oakand, Chemist and Druggist, Nottingham. (Aged 76.)

Correspondence.

Revision of the British Pharmacopoeia.

SIR,—Mr. E. C. Angel, in the Pharmaceutical Journal of the 24th instant, refers to Mr. J. C. Hyslop and others to my paper on the preparation of ointments. Since the paper in question appeared (April 14), several correspondents have written to promote the methods there suggested. In the Journal for September 15, Mr. Hyslop, in reply to Mr. Angel’s letter, says he had read my paper, but having reason to disagree with almost every one of the statements therein, he thought it best to take no notice of it. He is“ very hard” on my paper. However, as I said when I read the paper, it was with diffidence that I submitted my suggestions, because, although based on results obtained by careful experiment, they were contrary to accepted methods, and I have been quite prepared for adverse criticism. I am only sorry that Mr. Hyslop’s criticalism is not based on actual trial of the methods instead of on his “having reason to disagree with my statements.” It is hardly necessary for me to say that boric ointment is not of a sort to be made by my method. In this connection I think Mr. Hyslop scarcely appreciates what is meant by aeration when he says he saw no signs of it in the ointment after stirring till cold in a warmer. I confess I do not see how it could fail to be very well aerated under the circumstances. Let me ask Mr. Hyslop to prepare a sample of resin ointment by his formula (Pharm. Journ., August 25) and method, and a sample by the same formula, but allowed to cool in the manner suggested in my paper, then favour the readers of the Journal with his opinion of the comparative pharmacetical merits of the two ointments. My desire is to get at the best methods, and not to push a fat of my own, and I should be glad if some of those who desire to improve the Pharmacopoeia would at least give the methods suggested in my paper a trial, in preparing the ointments for which they appear to be applicable.

Edinburgh. Peter Boc.

SIR,—In reference to the notes on ung. ac. boric. and ung. ac. carbolic., made by Messrs. Hyslop and Clower, I beg to say that I am a small quantity of glycerin, about 3iv. to 3xiv. of the present ingredients ordered, be added. With this addition, and prepared by means of a water-bath, perfect ointments are obtained, and are much preferred to the ointments made without the glycerin. Samples of the ointments here forwarded have been made as above, and taken from my stock.

Croydon.

H. Long.

* * * The specimens of boric and carbolic acid ointments sent are of very satisfactory consistence.—[Ed. Pharm. Journ.]

Emplastrum Cantharidis, P. B.

SIR,—In reply to Mr. Mason, I suggest lack of time as a possible cause of failure. If practicable, I always inquire if the doctor has ordered the blister to be applied for any particular length of time, and, in the absence of such instructions, recommend seven or eight hours. More than once, in the absence of this advice, the blister would have lasted “about half-an-hour” in which to act, and of course would have failed. Blisters are usually spread on adhesive plaster, leaving a good margin to keep them in position.

Northampton. J. Clower.

Answers to Correspondents, etc.

David S. Robertson.—Please read the concluding paragraph of editorial article on page 231 last week, also the first note on page 135 (August 18). All information sent in response to the latter, and complying with the conditions laid down last week, was duly utilised. We were dealing with education during apprenticeship, and records of “passes” do not interest us.

J. H. Hart.—Thanks for your suggestion. The matter you refer to was already under consideration.

“Clifford.”—Diplotis babingtonii and Ergéron acris.

Books, etc., received.

Notices to Contributors.

••• Communications should reach the Editorial Department, 17, Bloomsbury Square, W.C., before noon on Wednesday, if publication be desired in the next issue of the Journal; though this cannot always be guaranteed.

Letters intended for publication must be written in ink on one side of the paper only, and be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.

All proofs are read by the editor, and the only notes taken of anonymous communications, and contributors are requested, as far as possible, to append their proper signatures rather than pseudonyms, a greater value being thus given to any opinions expressed.

All scientific and proprietary names should be written with extra care, those of plants and animals being underlined, and generic names alone commenced with capital letters.

Communications, Letters, etc., received, from Messrs. Hallaway, Hill, Newholmes, Parry-Owen, Woogger.
THE MONTH.

In the exhibition connected with the International Medical Congress at Rome, a product obtained from ergot was shown under this name by Böhringer and Söhne, of Waldhof. It is a yellow, amorphous powder, insoluble in water, dilute acids, or petroleum ether, but soluble in alcohol or benzol, and very readily soluble in ether. Its activity was stated to be very great in doses of four to eight centigrammes. In a recent report of Messrs. Gehe and Co., reference to this product is made, and the men expressed that apart from the various galenical preparations of ergot, the differences in the chemical products obtained from the drug by chemists are chiefly due to differences in the material operated upon, inasmuch as the varying influence of the conditions of climate, growth, preservation, etc., affect the action of the fungus upon the albuminous constituents of the grain. The greater the degree of moisture of the ergotised grain, and the less carefully it is dried, the more powerful is this action. The fact that Keller found only very weak ergotamine in ergot that was carefully collected and dried may be thus explicable, as well as the circumstances that some parcels contain only amorphous ergotinine while others contain it in a crystalline condition—some being quite inert while others are highly poisonous. If the preparation of products from ergot is thus rendered uncertain, still further difficulties arise from their liability to alteration. Thus, for instance, the alcoholic solution of some kinds of ergotinine rapidly turns red, and after some time gives no alkaloid reaction. In the absence of any trustworthy chemical test of identity, physiological experiment is the only means available. Cornutine appears to be a product of the alteration of ergotnine. Sphaecolinic acid, again, has only been obtained in the form of a dark coloured resin, and as it is rendered immediately inert by contact with alkalies, all attempts at purification have been fruitless. In operating upon a large quantity of ergot, Messrs. Gehe and Co. have obtained a product presenting the characters attributed to ergotamine, and behaving as an acid. They offer to provide any men with a supply for the purpose of testing its physiological action.

Hydroxylamine and its Decomposition.

In a paper read before the British Association, Dr. L. de Bruyn stated that the distillation of free hydroxylamine should be conducted at low pressure, since the base is violently explosive. Explosion occurs spontaneously at about 130°, and if the substance be heated to 70° or 80° an explosion may occur, the decomposition raising the temperature. Hydroxylamine is an endothermic compound, and can be transformed totally into gaseous products. Oxidizing agents, such as potassium permanganate, chromic acid, etc., act violently with the free base. Metallic sodium acts similarly, producing a flame, and if ether be also added a white substance, NaONH₂, is formed and explodes in contact with the air. The solvent properties of the free base almost equal those of water, and it can occupy the place of the water of hydration in salts. Though a strong reducing agent, free hydroxylamine is itself reduced by means of zinc dust, ammonia and zinc oxide occurring as the end products of somewhat violent reaction (Chem. News, lxx., 111).

Synthesis of Saligenin. By the condensation of phenol and formic aldehyde, L. Lederer (Münch. Med. Wochenschr., 1894, p. 619) has succeeded in producing saligenin, which may be regarded as phenol in which one hydrogen atom has been replaced by the methyl alcohol rest, CH₃-OH:—

\[
\begin{align*}
\text{CH} & + & \text{H} \\
\text{HC} & \text{C} & \text{OH} \\
\text{HC} & \text{C} & \text{H} \\
\text{Phenol.} & & \text{Formic aldehyde.}
\end{align*}
\]

On the assumption that saligenin is the substance which acts when the glucoside salicin is administrated and undergoes decomposition in the organism, it is supposed that it might be used medicinally with greater advantage and in proportionately smaller doses than salicin, which yields only 43 per cent. saligenin. The bitter taste of saligenin is very much less pronounced than that of salicin, and Lederer considers that owing to its relation to phenol, saligenin may also have some antiseptic properties. Products of analogous character are produced synthetically in the same way as saligenin by the condensation of formic aldehyde with the cresols, thymol, carvacrol, guaiacol, eugenol, etc., but the question whether these products have any practical value therapeutically has not yet been investigated.

Cadmium Salicylate. This salt is prepared by the action of salicylic acid upon cadmium hydrate or carbonate, or by precipitating barium salicylate with cadmium sulphate. When chemically pure it forms fine white tabular crystals which melt at 300°, and dissolve in 24 parts of water at 100°, 88 parts at 25°, and 90 parts at 0°. The compound is also soluble in alcohol and in ether, more freely when warm than cold; it is very soluble in warm glycerin, without precipitating on cooling, but is insoluble in chloroform or benzin. According to Cesaris, it possesses a much more energetic antiseptic action than the other salts of cadmium, and gives good results in the treatment of purulent ophthalmia and other disorders (Boll. chim.-farm. and Répertoire, [3], xvi., 421).

The struggle between the Le Blanc and Solvay processes for the manufacture of alkali is now likely to be participated in by a third competitor for favour, and whilst the two older processes excel each other in the economical production of chlorine and soda respectively, the new electrolytic process originated by Mr. H. Y. Castner, of the Aluminum Company, Oldbury, Birmingham, seems likely to prove a dangerous rival in both respects. It is stated that recent experiments have resulted in the production
of solutions which on evaporation yielded a solid caustic of 99·5 per cent., whilst the gas produced contained 95 to 97 per cent. chlorine. The essential feature of the process appears to be the employment of a moving body of mercury, which completely separates the products of electrolysis, and takes the place of a diaphragm, the amalgam formed being decomposed as rapidly as it is formed. According to the Times report, which is not very clear, the cells employed are divided into three compartments, and are capable of being continuously rocked or tilted, so as to give the contained mercury a flowing motion from side to side. The two outer compartments contain the carbon anodes and the alkaline chloride solution; the middle one an iron cathode and the caustic solution. The saline solution is continuously circulated through the outside compartments and, after being electrolysed, is returned to saturators, where it is recharged with salt. The electric current liberates chlorine gas, and at the same time sodium amalgam is formed, and subsequently decomposed. The process is continuous, and it is said that the electrical efficiency is 89·9 per cent. No hypochlorites are produced, and the electro-motive force required for each cell is low. With thirty cells the daily output is stated to be 1200 lbs. of pure caustic soda and 1000 lbs. of chlorine, with an expenditure of 110 l.p.

L. Vignon, continuing his work on this subject (see Ph. J., [3], xxxvii., 629), points out that the decomposition of sublimate solutions is principally due to alkaline substances in the water employed or the glass of which the recipients are formed, a limited quantity of such alkaline matter sufficient to cause the precipitation of a relatively considerable amount of mercury. On the other hand, hydrochloric acid and alkaline chlorides increase the stability of such solutions, the first by saturating the alkaline precipitates, and the chlorides by their solvent power. As the result of a series of experiments he finds that ammonium chloride prevents precipitation by ammonia or albuminous matter in the water, but fails to prevent the action of soda or sodium carbonate. Sodium chloride, on the other hand, fails in the case of ammonia and soda, but prevents precipitation by sodium carbonate and albumin. By combining the chlorides of ammonium and sodium, therefore, precipitation by any of the substances mentioned is prevented as well as by hydrochloric acid. The two formulae recommended are as follows:—(1) Mercuric chloride, 1 Gm.; ammonium chloride, 20 Gm.; sodium chloride, 10 Gm.; distilled water, 1 litre. (2) Mercuric chloride, 1 Gm.; hydrochloric acid (at 20°C Baurné), 1 C.c.; distilled water, 1 litre (Journ. de Pharm. et de Chim. [5], xxx, 111).

Dr. H. Meyer has applied the name "tannigen" to an acetylated compound of tannin. It is a greyish-yellow, tasteless, and odorless powder, very slightly hygroscopic, insoluble in cold water, somewhat soluble in warm water, but dissolving readily in alkaline liquids, such as solutions of sodium phosphate, carbonate, or borate. When boiled with these solutions it is decomposed into cotic and gallic acids. It is recommended for use in cases of chronic diarrhoea, its superiority to tannin depending upon the fact that it passes through the stomach unaltered, only exercising an astringent effect in the intestines, where it is decomposed by the alkaline fluids present. It may be given in doses of three to four grammes daily for a prolonged period, without causing any inconvenience (Bull. com., viii., 373).

The preparation introduced under this name as a remedy for coughs is a saline compound of antipyrine and mandelic acid (C₆H₄O₂). It is stated to be very much more effectual than antipyrine. For children under one year the dose is from one-third of a grain to a grain and a half two or three times a day; for children over four years, seven grains several times in the day (Pharm. Centr., xxxx., 632).

Purity of Flour and Yeast. 
M. Rondelet proposes to examine flour and yeast for mineral matters by a process akin to those employed in microbiology. A little of the suspected material is placed on a slide, and one or two drops of an aqueous solution of aniline and alcoholic fuchsin solution are then added, and followed by an equal quantity of tincture of iodine and distilled water. On applying a cover glass and examining, the cellulose appears reddish-brown and starchy matter black; but any mineral matter present will be yellowish, like the background of the preparation. The addition of a drop of water clears the preparation, crystals appearing with their normal tint and sharply defined. It is stated that in less than five minutes it is thus possible to decide whether a flour contains plaster, barium sulphate, china clay, etc. (Journ. de pharm. d'Anvers, 1, 363)

Filtration of Water. 
P. Miquel publishes the results of a series of experiments bearing upon the sterilisation of water by filtration, performed with a modified arrangement of the Chamberland bougie. The space between the bougie and its enclosing case was filled with coarse sand, and before the water was admitted it was passed through a cylinder, 0·10 M. long, which contained a layer of fine sand, 0·07 M. thick, and another of animal charcoal, 0·03 M. thick. The water was sterilised at 100°C prior to the experiments, and for purposes of comparison a second Chamberland bougie was used in the ordinary way, the filtered products from the two being tested side by side. While the filter enveloped in sand delivered water showing no trace of bacteria until the twelfth day, when 60 per Cc. were present, that passing through the other was found to contain 20 per Cc. on the second day, and the number increased rapidly subsequently. Again, whilst the flow of water from the naked bougie was reduced to half by the fifth day, that from the sand-enclosed one had increased on the fifteenth day to double what it was on the first (Journ. de pharm. et de chim., [5], xxx, 219).

Ice Crystals on Plants. 
C. Ely deals with the formation of ice crystals on the surface of plants, under certain conditions of weather and surroundings, and states that the conditions of the phenomenon are that the temperature in the soil surrounding the roots of the plant must be above zero, as also must be that of the central parts of the water-conducting tissues, and that the soil must be sufficiently charged with
water. The cold causes a contraction of the tissues, and diminishes turgescence and the permeability of the cell-walls to water. As the contents of the peripheral ends of the medullary rays freeze, expand, and are pressed forward, the stem splits at the point of least resistance, and the ice forms a layer covering the whole surface of the wound, the internal pressure supplying water which is drawn up by capillary forces. In many plants, however, splitting of the stem does not occur, and further investigation and explanation is required in such cases (Bot. Gazette, xxi., 321).

Cerus (var. stomoliferus, F. M. Bailey) has been subjected to examination by Dr. T. L. Bancroft, of Brisbane. He has extracted from the plant a crystalline principle which is very bitter, and is apparently a glucoside. The crystals are very soluble in water, less so in dilute spirit, almost insoluble in ether or chloroform. Strong sulphuric acid gives no colouration with the crystals, but ammonia gives a yellow colour. Auro chloride and tannin give slight precipitates with the solution of the crystals, but mercuric chloride gives none, nor does potas- sium iodide of mercury. The crystals are deliquescent, and when exposed in a thin layer to the air for a few days they assume a green colour. They reduce an alkaline solution of cupric oxide. At first Dr. Bancroft suspected that this principle might be identical with ouabain, since the genus Cerus is closely allied to the Solanaceae, and the alkaloidal extract of the bark rapidly killed frogs when subcutaneously injected, the heart stopping in systole and the muscles being pale and paralysed. He now believes, however, that it is quite distinct chemically. Dr. Bancroft suggests that the allied species, C. clytoplicum, which is used in Mauritius in diseases of the urinary organs, might be worth trial in the United States, the Brisbane plant being scarcer.

Specios Strophanthus: An illustrated monograph of this genus has recently been published by Dr. Franchet in the Nouvelles Archives du Museum. S. boivinii, H. Baill., S. tholloni, Franch., and S. courmontii, Sacleux, are remarkable for not having tailed appendages to the corolla lobes, which in the first-named species are quite obtuse, whilst in S. borleri, Franch., S. congoensis, Franch., they scarcely exceed 1/8 inch; in S. parviflorus, Franch., and S. amboensis, Engld. and Pax., and S. ogovenis, Franch., they are about 1/3 inch, and in S. bracteatus, S. tholloni has the long-tailed anthers of the roSELLia section, and long tapering scales in the throat of the corolla, nearly equaling the lobes in length, and the other species present every gradation in the length and shape of the corolla scales and in the length of the awn of the seed, showing that the species, although exhibiting great variation in the shape and size of the flowers, form a closely connected series. Dr. Franchet points out the curious fact that there is a relation between the glabrous character of the seeds and the presence of the anthers which crowns the connective of the anthers. Guided by this relation, Dr. Franchet concludes that the only two African species thus furnished, viz., S. gratus and S. tholloni, are the sources of the smooth

strophanthus seed of the Gaboon. This monograph forms a most valuable addition to our knowledge of the genus, the species of which, as now enumerated, have reached the number of thirty-five.

Castor: Gordon Sharp and Hoscose have examined a number of specimens of Grandiflorus. This plant—the night-blooming Cereus (Caecetus)—but failed to find in them either glucoside or alkaloid. They have found, however, that the plant contains a series of resins, one or more of which are soluble in normal saline solutions, and such medicinal activity as it possesses is probably due to these. Feces and gum are also present, together with a small amount of sugar. The resins are completely removed by absolute alcohol, almost wholly by absolute ether, less perfectly by chloroform or by rectified spirit. Pharmacological experiments, of which details are given, were performed with solutions of the pure resinous extract in saline solution (0·5 per cent.). The resins had little or no effect as compared with digitalis, and the result of the experiments appears to indicate that the plant is pharmacologically inert. At most it has some slight diuretic action (Practitioner, ii., 161.)

Thermophilus: Thermophile have made experiments with a view to studying the range of temperature at which it is possible for bacteria to grow. After inoculating agar-agar with garden soil, they found that an abundant growth of bacteria was obtained at the comparatively high temperature of 60° to 65° C. To such organisms the term "thermophilic bacteria" is applied. They are widely distributed in nature, being found in fœces, sewage, Thames water and mud, surface soil, and soil at a depth of five feet. Dust from the streets invariably contains them, and they are also present in sea water. In fact, they may almost be termed ubiquitous. About twenty different forms of thermophile bacilli have been isolated, all, with one exception, being spore-bearing organisms. They will not grow at or below blood heat. Some liquefied gelatin, others did not. A number of them curdled milk, and one converted starch into sugar. In broth and agar cultures a putrefactive decomposition took place, iodol and sulphuric hydrogen being produced. The organisms also produced an active decomposition of meat and blood albumin, and several of them produced a fermentation of cellulose. They are said to exercise perfectly all the functions common to saprophytic organisms, at 60° to 65° C., that is a temperature which is usually fatal to the life of cell-protoplasm (Br. Med. Journ., no. 1760, 644).

In a paper on the function of the Fat in the sweat-glands in man, Dr. P. G. Unna Sweat-Glands, gives a summary of the researches on this subject, and devotes special attention to the secretion of fat. He is of opinion that it is irrefutable that the ordinary sweat-glands in man secrete fat, and shows that this can readily be proved by treating sections of skin or the sweat of the hand with oeric acid. The fat, though similar to that of the sebaceous glands, is described as differing from it in the same way that stearic and margaric acids differ from oleic acid (Br. Journ. Dermatology, vi., 257).
A NEW SULPHURETTED HYDROGEN APPARATUS.*
BY J. F. LIVERSEBOGE, F.I.C.

Most of the arrangements used for preparing sulphuretted hydrogen on a small scale suffer from either or both of the following disadvantages:—
(1) The size of the hole through which the ferrous sulphide is introduced to the generator requires the sulphide to be crushed rather fine, with the result that there is a good deal of powder which gets into the acid bottle and continually generates the gas. (2) The tube between the acid bottle and the generator is small, and is frequently stopped up.

To avoid these troubles, some four years ago I devised the following arrangement:—

The generator, A, is a pint green glass wide-mouth bottle, with broken glass at the bottom an inch deep, and on it the lumps of sulphide; as the neck is 1\(\frac{1}{2}\) inch in diameter, fair sized pieces can be put in. This is closed gas-tight with a cork or rubber bung coated with paraffin wax; through it pass two glass tubes; one, just through the cork, is connected with a pint Woulff’s bottle, F, for washing the gas; the other, \(\frac{1}{4}\) inch inside diameter, reaches nearly to the bottom of the generator, and is connected by means of a T-piece, B, with a large glass funnel, D. The other leg is closed by a rubber tube and pinchcock, C.

A little water is put in the funnel and commercial hydrochloric acid added. As the gas is generated, the liquid is forced up into the funnel, the layer of glass at the bottom preventing the sulphide soaking in the acid. A glass stopcock, E, is used for regulating the supply of the gas. When no more gas is required, the pinchcock, C, is removed, and the acid runs out through the side tube into a bottle for future use with more acid if necessary.

A CONSTANT LEVEL APPARATUS.*
BY F. C. ROBINSON.

The following apparatus, which I have used for some time, may interest other chemists; hence the following sketch and description:—

B is a glass tube about 2-5 Cm. diameter, into which is passed the small tube A through a cork. A side tube C extends out about ten Cm., and is of much larger bore than A. Upon the lower end of B is sealed a small glass tube H, which is bent up until opposite C and then turned at right angles. Connected with H by a rubber tube is a tube D of equal bore and about twenty-five Cm. long. Upon the other end of D is a bulb E, five Cm. in diameter, turned down at right angles as shown in the cut. At the point G is a short tube, and just beyond it at K, the tube D is closed up by melting it together. F is a water-bath, through one of the openings of which E passes and floats upon the water. As the water rises in the bath, E, of course, floats higher and raises the tube D. The rubber connector holds D upright and allows it to move. If B is clamped so that C and D are upon a level, and the tap opened so that water flows into B through A, it will run out of both C and D, but of course D will soon float up so high that no water will run through it, and all will discharge at C. Now heat the bath, and as soon as evaporation has lowered D, sufficiently more water will run into the bath to take the place of that evaporated. A small stream of water flows constantly out at C and into the sink, but it need be very small indeed.

If the bulb E enters the bath through a place needed for evacuations, a small copper cylinder slightly larger than the opening, and having a narrow strip cut out of it for D to move up and down in, may be placed over it as in the cut. Of course, the float may be placed in a side tube soldered to the bath with water-connection to it. If one cannot make it of glass it could easily be constructed of metal by any tinsman.

I find, also, that the same idea works admirably for constant feeding of a small platinum dish in evaporating large quantities of water or other liquids for analysis of residues. In such cases the tube D is directly connected with a bottle holding several litres of water in the manner illustrated in the cut at the right. As D falls through evaporation of the water in \(w\), air enters through L and water drops out at \(w\) till \(D\) rises so that \(w\) is higher than the bottom of L when it stops, and thus the level in \(w\) is constant. In this case the tube \(D\) is very small, so that the bulb can be

* From the Journal of the American Chemical Society.
very small and still hold it up. In the one I use the bulb is only 1.5 Cm. in diameter, and the tube is so close to it that it can be used in a crucible. It is very easy to clean the float from the slight residue clinging to it at the end.

I use the same apparatus for washing precipitates with a large amount of water, placing the bulb in the funnel on the surface of the wash-water.

SOME FALLACIES IN THE TESTING OF ESSENCE OF LEMON.*

BY ARTHUR A. BARETT,
Pharmaceutical Chemist, Messina.

The object of this short note is to draw attention to the absolute worthlessness of the tests in common use for the examination of the purity of essence of lemon.

Until a few years ago almost every buyer contented himself with rubbing a little on his hand and smelling it, but repeated cases of essence "changing" into turpentine have forced upon them the desirability of relying on some chemical or physical test which should be more accurate.

As in so many other cases, Germany led the way, and a well-known firm advertised largely, recommending the use of the polarimeter as a test.

Although it is the object of this note to show how entirely useless is this test, yet it undoubtedly has done good work, and has prepared the way for the acceptance of a really scientific test which, in my opinion, is certain to be evolved during the next year or two.

During the last two years I have had a polarimeter in almost constant operation, and during the lemon season have often examined as many as twelve samples of essence a day with it.

The result has proved that genuine essence may differ in its optical activity between +57° and +72°. As the addition of 5 per cent. of raw turpentine to genuine essence only makes a difference of 4 or 5 degrees in the rotation, it is clear that such a test is one that cannot be relied on.

As regards the limits above mentioned, it is only fair to say that they are exceptional, and in the case of the higher reading I cannot absolutely guarantee it, but +69° is not so uncommon. In the case of the essence with the low reading of +57°, I was so altogether incredulous that I had some of the lemons brought to my works, and the essence extracted by my own employees, with the same result.

It is rather remarkable that the maturity or otherwise of the lemons does not materially affect the reading, but the district in which the lemons grow makes a great difference, as may be seen from the following table, which gives the average results obtained:—

| Essence from Asi Reale and district... | +61° |
| Immediate vicinity of Messina... | +62° |
| Giareli Giardini Mascoli... | +63°—64° |
| Barcellona (Sicily)... | +66°—67° |

All the above measurements were made with a 100 Mm. tube and ordinary artificial light. Where great accuracy is required sodium light is desirable, but I did not find such a refinement necessary.

During the present year several Messina firms have invested in polariscopes, and being without scientific assistance some very curious mistakes have resulted.

In a letter to the American consul, published in the consular reports for May, 1894, by the Department of State at Washington, which, I may say, contains a valuable report on the Messina essence trade, one of them writes:—

"The requisites which modern science has found to distinguish the adulterated essence from the pure must be"

| Essence of lemon |  |
| Specific weight | 0·8857 | 15°C |
| Opt. rotation | +62° | 100 Mm. tube |
| Index of refraction | 1·478 | 20°C |

It is clear, therefore, that this firm must continue to buy its lemons from the same district, or by its own tests its essence may be rejected as adulterated.

The second objection to the general adoption of this test is the great assistance which it gives to fraud.

The remark is not original, but testing by the polarimeter is like mixing black and white, and when you see grey, thinking you have got purity.

In this case everything is ready to hand for the mixing process. Turpentine as used in Messina is always invo-rotatory, whilst essence of sweet orange is powerfully dextro-rotatory, +98° being the average. It is, therefore, only the matter of a simple proportion to get a mixture indistinguishable polarimetrically from essence of lemon. I would state the exact proportions, but the object of this note is not to assist fraud but to expose it.

Shortly after the "boom" in polariscopes, which took place here at the beginning of this season, I was waited on by one of the local turpentine refiners, who told me that he had modified his "refining" process in this way by adding to it some very cheap distilled essence of orange, and it was now absolutely impossible to detect its presence. In fact, he declared that business being slack he had himself mixed essence, and sold it to a Messina dealer as genuine, after he had tested it with the maschinette, as they call it here.

In any other country the avowal of such a proceeding would very likely lead to legal proceedings, but here it is only considered as being sharp business, the addition of turpentine to essence being considered to be almost sanctioned by long use.

The Refractometer.—During the current year another machine has been introduced here for the optical examination of essence. It is a pretty little machine, and only requires a drop of essence for a test. I commend its use by chemists examining oils generally, but for the examination of lemon I do not find it of any use. A few experiments showed me that of the two kinds of turpentine used here, ordinary French and the kind sold as "citronina," the one increased and the other diminished the reading, and the presence of 5 per cent. of either made only a difference of a fraction of a degree. Further, the instrument is extremely sensitive to changes of temperature. For the present, therefore, my instrument is relegated to the museum.

* Paper submitted at the Oxford meeting of the British Pharmaceutical Conference.
Perhaps the commonest test known is the specific gravity, and this is literally subject to change with every wind that blows. Just think of the enormous surface exposed to the air by a garden of lemons, and think that every drop of essence is pressed out by a man’s fingers, runs over his hand, and is finally absorbed by the pores of a sponge. Then remember that in Sicily we get the “sirocco”—a hot wind from the Sahara—and you will not be surprised that evaporation at such times is considerable, with increase of specific gravity. On such occasions the yield of essence will fall five or even ten per cent., although every precaution may be taken in the workroom to exclude draughts.

The only remaining test in common use to which I need now refer is the test for mineral oil with alcohol or by evaporation on a piece of paper. Both of these tests are delicate and reliable.

I prefer to use filmy, or the paper used for packing lemons, for making this test.

The various empirical tests—butterate of copper, etc.—proposed from time to time, which may be found scattered up and down the periodical literature of the past, are not in common use, nor do they merit attention.

The direction in which progress is to be looked for now is chemical rather than physical—optical activity, refraction of light, and specific gravity have all been tried in turn, and though not without some value, leave much to desire. The determination of the citral naturally presents itself, but it is present in too variable a proportion to be useful as a test of genuineness. Its utility is rather as an assay. I may mention in passing the work of Messrs. Benedikt and Straube (Monatsh. f. Chemie, April, 1893). The recent memoirs have probably escaped me, owing to my being so far away from any scientific library.

What is wanted is to select some one constituent which is present in constant proportion and determine the amount of this.

Although in the commencement of this paper I looked forward to the near advent of a test which should be of some use, and have sketched out the lines on which it should run, yet chemical science will never be able to say more than this essence contains or does not contain an added adulterant, or this essence contains so much citral and that other so much.

The fine gradations of quality which make the essence of one maker preferred and the essence of another only saleable at a reduction are, and always will be, incapable of exact measurement.

Compare the fragrance of essence made with scientific care from fruit freshly gathered off the trees, and rapidly filtered and hermetically sealed down, with the essence made by the ignorant “trapetan.” His fruit is stale, perhaps half rotten; he works in a hovel innocent of drainage; his sponges are old and never washed, full of a putrefying mass of lemon lice (pidocochia), bird droppings, and all sorts of dirt.

Is the essence he makes pure? Of course it is, if he puts nothing in. But is it worth the same as the other? Of course not.

The Proposed Imperial Pharmacopeia.

The Sub-committee of the Melbourne and Victoria branch appointed, in accordance with the request of the General Medical Council, to make suggestions with a view of assisting the Pharmacopoeia Committee of the General Medical Council have now presented their report. Our Melbourne correspondent writes that the report has been conscientiously and carefully compiled, and contains a good deal of information which is bound to be of service to the Home Committee. The recommendations consist:—

1. In enumerating a large number of medicinal plants in the B.P. which grow in this colony equally as well as in the regions recognised as official, and in suggesting that, as far as Victoria is concerned, the present restriction as to growth and preparation should be removed.

2. To introduce the preparations of duboisina as official. The dose of duboisina would be $\frac{1}{4}$ or $\frac{1}{2}$ of a grain internally. In ophthalmic application one or two drops of a solution four grains to an ounce.

3. To adopt the metric system of weights and measures, and altering this, that the strength of the liquids of the alkaloids revert to gr. j in $\frac{1}{3}$.

4. That certain official formulae for eucalyptus alone be used.

5. That a number of preparations and drugs at present unused in practice and unnecessary in therapeutics be omitted from the new pharmacopoeia.

6. That adeps lanei and paraffinum molle be altogether used as the bases for ointments, and that cacao butter be recognised as the sole basis for suppositories.

7. That the tests for chloroform, carbolic acid, and other drugs be improved, and that there be mentioned with the test the specific impurity of which it is destined to show the presence or absence.

8. That the standardisation of drugs, such as opium, be extended to other powerful drugs, such as saponine, digitalis, etc.

9. That a number of new drugs and preparations be made official, such as chloral eum-camphora, some of the elixirs and syrup compounds, $\Delta$ naphthol, salicylates of bismuth, salol, resorcin, ichthyol, ethyl chloride, malt extract, a solution of copalina, cubeb, and balsam, and others.

10. That the list of tabellae for hypodermic use and the trochees be increased.

11. That, like the decoctions, all the infusions be made up to a definite quantity.

12. That in certain drugs (tabulated) the maximal dose should be increased, and in others the minimum dose lessened, and other inconsistencies rectified.

13. That an excessive dose be not dispensed unless it has been intimated or attention otherwise drawn to it by the prescriber.—British Medical Journal.
A FACULTY OF PHARMACY.

In the course of the discussion on the proposal to admit associates to full membership of the Pharmaceutical Society, the question was raised as to the desirability of further distinguishing those who are now known as "pharmaceutical chemists," after passing the higher and voluntary examination of the Society. Of the various suggestions made, none is more attractive than that a degree should be conferred upon pharmacists, but the fact must not be lost sight of that a degree to be of any real value must be conferred by a body properly constituted for the purpose, i.e., by a university, and should not be granted until after the candidate has responded satisfactorily to the application of the most thorough tests as to capacity and training. That the Pharmaceutical Society of Great Britain is not in a position to confer degrees that would command a proper measure of respect should be obvious to everyone concerned, as also that the requirements of its "Major" examination are not alone sufficient to entitle successful candidates to the suggested distinction. It is generally understood in this country that the holder of a degree has received a good general education in all subjects in any way connected with those in which he has specially graduated, and this much cannot always or even often be said of the average "Major" man, although he may be all that is desired as a specialist.

As to how the necessities of the case may best be met, the impending re-organisation and extension of the University of London would seem to offer an opportunity which might well be taken advantage of. There is no valid reason why there should not be in this country, as abroad, a faculty of pharmacy connected with one of the great universities, and that of London single itself out as the one with which pharmacy could with the greatest propriety be affiliated. For, as the University of London now imposes no conditions as to how or where candidates for degrees have obtained the necessary instruction, whilst in the re-constituted body it is proposed in addition to make special arrangements for students who can produce evidence of having passed through a definite curriculum, so the degree in pharmacy might very properly be conferred — until such time as a compulsory pharmaceutical curriculum may be enforced — in the case of either "attached" or "unattached" students. To meet the requirements of the former the School of Pharmacy and any similar institutions subsequently organised might be raised to "collegiate rank and affiliated with the University, after affording satisfactory proof that the means at their command and the proposed courses of study would suffice for the end in view. Of course, it is taken for granted that the existing arrangements as to the legal qualifying examination need not be interfered with, though it might be found desirable and necessary to raise the standard to that of the present "Major" examination, whilst considerably extending the scope of the "First" examination, and insisting upon three years being devoted to practical work in the pharmacy between the times of passing the "First" and qualifying examinations. Since, too, most students in pharmacy would probably like to feel free to proceed to the degree examination, it would perhaps be found desirable, sooner or later, to abolish the existing "First" examination entirely, and substitute for it the London Matriculation examination. To pass this, as is well known, candidates must show a competent knowledge of Latin, French or German, English, Elementary Mathematics, Mechanics, and Chemistry or Botany, etc.; all of which are subjects with which, even now, it is desirable and almost essential that pharmacists should be properly acquainted.

Assuming the undergraduate to have undergone the period of pupillage and obtained his legal qualification as a pharmacist, entitling him to perform all the functions and enjoy all the privileges now peculiar to "chemists and druggists," and "pharmaceutical chemists," it remains to consider what more should be expected of him to entitle him to the university degree. Not less than twelve months after qualifying as a pharmacist he should be entitled to present himself for an "Intermediate Scientific" examination, mainly practical, in mathematics, mechanics, general biology and elementary physiology, experimental physics, and chemistry. French or German should also be included, whichever had not been taken at matriculation. Finally, for the pass examination, open after another twelve months
interval, the candidate should be required to show a fully competent knowledge of experimental physics treated mathematically, advanced chemistry, particularly organic and analytical, and systematic, physiological, and histological botany, all the subjects being dealt with both theoretically and practically.

It is doubtful if any advocates for a degree in pharmacy have realised how much should be required of candidates for the degree, but it is certain that nothing less than suggested in the syllabus outlined above would properly suffice. If there were any consensus of opinion amongst British pharmacists that a degree in pharmacy was a desirable thing, to secure which they were prepared to greatly extend their educational course and perform a vastly increased amount of scientific work, there is little reason to doubt that the necessary arrangements could be made to give effect to such laudable intentions and desires. Unfortunately, however, the general tendency is too much in the direction of unduly limiting the preparatory professional work, and the desire for the honourable distinction suggested is usually associated with a decided disinclination to become fitted for it. Nothing like the proper amount of scientific training is undergone by the average pharmacist at present, and it would be extremely undesirable to attempt to base any project for a degree on existing foundations. Briefly, it may be stated that the candidate for a degree in pharmacy should, at the outset, be a fully qualified pharmacist, knowing much that the pharmacist is not now required to know. He should afterwards pass examinations equivalent in value to the intermediate and pass examinations of any degree now granted by the University of London. The possession of the degree would then distinguish its holder in the manner desired, and the degree itself would possess an absolute value, on account of the work done to obtain it, no less than the position of the body conferring it.

PATENTS IN PHARMACEUTICAL PREPARATIONS.

At the meeting of the Apotheker Verein, in Oaseal, Professor Beckures drew attention to cases in which the claims of patentees involve interference with the pharmacist's right to carry out operations falling within the ordinary exercise of his art. As an instance of this kind he referred to the claims made by the manufacturers of lanolin that the intermixture of purified wool-fat with water constitutes an essential feature of their invention, and that consequently the kneading of any purified wool-fat with water amounts to an infringement of their patent rights. He pointed out that according to the specification of the patent lanolin is represented as presenting, under the microscope, the appearance of a homogeneous mass, and that this statement is suggestive of the assertion that the combination of purified wool-fat and water termed "lanolin" is of a peculiar nature and something not previously known. That, however, he held to be by no means the case, and he further stated that the combination of wool-fat and water is, from a chemical and physical point of view, nothing different from the combination of fat and water in the well-known article called cold cream. The protection accorded by this patent to the incorporation of water with wool-fat is therefore an invasion of the pharmacist's right to exercise his art. Professor Beckures referred to the well-known fact that though fats and similar substances are not spontaneously miscible with water, it has long been known that they can be brought into mechanical intermixture by stirring them together. Microscopic examination shows that the mixture thus effected is not homogeneous, inasmuch as the particles of fat and those of water can be distinguished side by side. In this respect wool-fat is no exception. It does not any more than other kinds of fat or fatty substances form a homogeneous mixture with water. When olive oil, almond oil, or lard—all of which are used as the basis of ointments—are shaken or rubbed with water, the emulsion formed may be seen to consist of oil globules swimming in water. The whiteness of such an emulsion is a consequence of the total reflection of light. In the same manner by rubbing linseed oil, spermastoi, wax, or mixtures of these materials, with water, the emulsion produced is seen to consist of minute globules of fat surrounded by water. Wool-fat behaves exactly in the same manner as other kinds of fat, and is in no way an exception to the general rule. Lanolin, therefore, is not a new or peculiar product, and it is in no sense different from any of the other mixtures of fat and water which have been prepared from time immemorial as the bases of ointments in pharmaceutical laboratories. So long as pure anhydrous wool-fat was not obtainable, there was some reason for using the material produced by the patentees of lanolin, but now that pure wool-fat is obtainable commercially, Professor Beckures considers that the claim to patent right as regards the admixture of water with it for preparing a basis for ointments becomes an inappropriate obstruction which would interfere with the right of the pharmacist to perform a well known operation.

THE BRITISH PHARMACOPEIA.

We are informed by the Registrar, acting on behalf of the President, of the General Medical Council, that the number of British dependencies from which communications have been received relating to the arrangements for the next issue of the British Pharmacopeia has been further
increased, reports having been received through the Colonial Office from the Governor of Hong Kong, the Board of Medical Officers appointed in Ceylon to report upon the subject, and the Governor of South Australia. The latter included replies from the Presidents of the South Australian Pharmacy Board, the Medical Board of South Australia, and the South Australian Branch of the British Medical Association. Through the Privy Council Office, a report has been received from the India Office of a Committee appointed in India to make suggestions in connection with the subject.

In these additional communications some new drugs and a few foreign species of British medicinal plants are proposed. Several new preparations are suggested, the omission of what are considered to be useless articles of the materia medica and useless components of old preparations is recommended, and a large number of amendments of existing formulæ are included, as well as a few adaptations of formulæ for suitable army and navy purposes. In all these communications, as in the former ones, local climatic conditions originate a desire for harder ointments and for non-drying extracts. Climate, however, varies so much in the different British possessions that some general permission to vary the proportions of hardening and softening components may have to be received instead of several slightly varying formulæ, or any one average formulæ. We understand that further replies are under consideration by the Government departments prior to transmission to the Medical Council. Details of the recommendations of the sub-committee of the Melbourne and Victoria branch of the British Medical Association are given at page 256.

SCHOOL OF PHARMACY.

As previously announced, the fifty-third session of the School of Pharmacy of the Pharmaceutical Society will be commenced on Wednesday next, October 3. The chair will be taken at the inaugural meeting at 3 p.m., by the President, Mr. Michael Cartright, and the distribution of prizes to the successful students of the past session will then take place. Afterwards, the inaugural sessional address will be delivered by Mr. Walter Hills, Member of Council. At the close of the proceedings, in which all pharmaceutical students are invited to take part, the Society's House will be open for inspection by visitors.

ADULTERATED PHARMACEUTICAL PREPARATIONS.

At the Skipton Petty Sessions several persons have been convicted under the Food and Drugs Act of selling adulterated tincture of rhubarb, paregoric, etc., and subjected to heavy penalties. The defendants were not in any of the cases tried registered chemists and druggists; but these convictions will no doubt appear in the Local Government Report as indicating the extent to which drugs and pharmaceutical preparations are adulterated, without any information as to the important fact that the defective articles were sold by persons who do not possess the requisite qualification to deal in articles of this kind. Attention has frequently been directed to this circumstance and it has been pointed out that the indiscriminate record of such cases of adulteration casts unmerited discredit upon the legally recognised vendors of medicines.

CONGRESS AT VIENNA.

The annual Congress on Naturalists and Physicians was opened at Vienna on Monday, in the presence of the Archduke Raimund, Prince Windischgrätz (the Prime Minister), and three other Ministers, and many of the highest Austrian Military and Civil functionaries. The attendance of members was very large, nearly two thousand five hundred tickets of membership having been taken. The inaugural address was delivered by Herr Hofrath Krenner. It was mainly a survey of the progress made by the natural and medical sciences since the Congress at Vienna in 1892, and of the part Austria had played in this field during the past fifty years. The Minister of Public Instruction and the Burgomaster of Vienna afterwards welcomed the Congress to the Austrian capital, on behalf of the Government and the Municipality. The delivery of lectures and reading of papers were then proceeded with.

CLASSES IN BACTERIOLOGY.

The new syllabus of the evening classes in bacteriology, conducted at King's College, shows that the course is still undergoing modification and extension. The class in general bacteriology will re-commence on October 15, and will be held on Monday evenings throughout the term, from 7 to 9 o'clock. The bacteriology of fermentation will be practically treated on Wednesdays, from 7 to 9 p.m., the class commencing October 17. Full particulars of these useful courses will be sent on application to Dr. R. J. Hewlett, Bacteriological Laboratory, King's College, London.

EDUCATIONAL FACILITIES AT PLYMOUTH.

We are asked to announce that the Technical Instruction Committee of the Borough of Plymouth has made arrangements at the Municipal School of Science and Technology to meet the requirements of pharmaceutical students in the district. The chemical and physical laboratories are well equipped, and provision is also made for the study of systematic and practical botany, zoology, and general biology. The materia medica class has the benefit of a well-arranged collection of specimens.

METHYLATED SPIRIT LICENCES.

Retailers of methylated spirit are reminded that the annual licences for the sale of this article, granted by the Inland Revenue authorities, are renewable on October 1.

GOVERNMENT APPOINTMENT.

We are pleased to learn that Mr. Joseph Henry Maiden, Curator of the Technological Museum, Sydney, and a Corresponding Member of the Pharmaceutical Society, has been appointed Superintendent of Technical Education under the Department of Public Instruction, Sydney.
The following is the programme of this Association for the half-session, October to December, 1894:

October 4.—Inaugural Address. By the President.
October 11.—Medical and Social Evening.
October 18.—Discussion: The Duties of the Pharmaceutical Society as an Educational Body. Opened by E. H. Gane.
October 25.—Paper: "Chemical and Pharmaceutical Signs and Symbols." By T. Tickie.
November 1.—Paper: "Sneezing." By Scanes Piper, M.A.
November 8.—Paper: "Recent Advance in Photography." By E. W. Hill.
November 15.—Annual Conversazione.
November 22.—Paper: "Surgical Dressings." By E. White, B.S.
November 29.—Short papers by members.
December 6.—Discussion: Can we stop "Company Pharmacy?" Opened by H. B. Care.
December 20.—Musical and Social Evening.

The meetings are held at 103, Great Russell Street, W.C., at 8.30 p.m., the chair being taken at 9 o'clock precisely.

**American Pharmaceutical Association.**

**A Microscopical and Chemical Examination of Cloves.**

BY HENRY KLEEMIR.

More than a year ago a sample of a splice was submitted to the author, an examination of which revealed the presence of a large quantity of starch. The question was then asked: "How much is there of this adulteration?" A quantitative answer was desired without a chemical analysis. This was the beginning of the present work, and very naturally the thought arose, is it possible to obtain quantitative as well as qualitative results with the microscope? The results are embodied in this paper—which is intended, however, merely as a preliminary paper—on the comparison of quantitative microscopical with chemical examinations, and it is hoped will reveal the possibilities of research in this direction. At the same time are given the results of analysis of some commercial samples of clove oil and cloves by Thom's method (with perhaps a slight modification) of determining the eugenol in the form of a benzoyl compound.

**Extraction of Oil from Cloves.**—10 Gm. of the powder were mixed with 10 Gm. of dried calcium sulphate, wrapped in filter paper and extracted in a Schubert apparatus by means of petroleum ether. Some of the ether was recovered, and the remainder was siphoned off by means of a siphon and a suction of air. The oil thus obtained had a viscous appearance, and on the addition of alcohol about 0-16 per cent. of a white resinous compound separated, which on the filter assumed the form of a very fine gauze. To this filtered solution from 8 to 10 Cc. of alcoholic potash solution (1 Cc. = 0.09856 KOH) was added. The alcohol was removed on a water-bath, and to the nearly dried mass from 2 to 2.5 Cc. of benzoic chloride was added. The mixture, in a flask similar to that in which the extraction had been done, was stirred with a glass rod until the reaction was complete. Water containing some KOH was then added, and the whole heated on a water-bath for a few minutes, then removed and placed in ice water, and when cooled the clear liquid decanted, and if there were any floating oily particles, these were removed in a separatory funnel by means of ether. This washing was continued three or four times, and finally the benzoic eugenol was separated from the water by means of a separatory funnel with ether. The ether was evaporated off (assisted by siphoning the vapour and the use of the suction of air). The mass on cooling crystallised. These crystals were dissolved in 15 Cc. alcohol (90 per cent.), heated to solution, and re-crystallised by placing in ice water and shaking the flask repeatedly. The solution was decanted and filtered through a small filter from the crystals, and the latter simply washed with an additional 15 Cc. of alcohol (90 per cent.). The crystals in the flask with filter paper were dried at 100°C. and weighed.

1 Gm. eugenol requires 341 Gm. KOH.
1 Gm. eugenol requires 883 benzoic eugenol.
5 Cc. alcohol (90 per cent.) will dissolve 110 Gm. benzoic eugenol.

\[
\text{CH}_3\text{OCH}_3 + \text{KOH} = \text{CH}_3\text{OCH}_3 + \text{H}_2\text{O} + \text{KOH}
\]

**OH**

**Eugenol**

**Potassium Eugenol**

\[
\text{CH}_3\text{CH}_2\text{OH} + \text{Cl} - \text{C} - \text{C}_3\text{H}_4 = \text{CH}_3\text{CH}_2\text{OH} + \text{KCl} + \text{OCH}_3
\]

**OH**

**CH_3**

**Potassium Eugenol**

**Benzyl Eugenol**

Thom's has worked out an algebraic formula for hastily calculating the results, which may be translated as follows:

- \( a \) = weight of benzoic eugenol.
- \( b \) = weight of oil taken.
- \( c = 0.110 \) Gm. for every 5 Cc. of alcohol used (being the weight of benzoic eugenol dissolved in 90 per cent. alcohol).
- \( x \) = per cent. of eugenol.
- Molecular weight of eugenol = 164.
- Molecular weight of benzoic eugenol = 268.

Then:

\[
268 : 164 = (a + c) : \text{weight of eugenol}
\]

Weight of eugenol = \( \frac{164(a + c)}{268} \).

b. \( \frac{164 (a + c)}{268} = \frac{100}{x} \).

\( x = \frac{164(a + c)}{268} \cdot \frac{100}{x} \).

\( x = \frac{100(a + c)}{678} \).

The following results have been obtained by this method from the commercial samples of powdered cloves and clove oil:

<table>
<thead>
<tr>
<th>Pow'd. Cloves</th>
<th>Per cent. of oil</th>
<th>Per cent. Eugenol</th>

<td>60.45</td>
</tr>
<tr>
<td>3</td>
<td>12.75</td>
<td>66.16</td>
</tr>
</tbody>
</table>

* This sample was determined by the microscope to contain powdered clove stems, although sold by a large house in New York as powdered cloves.
Coming to the subject of quantitative microscopical analysis, while accurate results may be possible, so far only approximate figures have been obtained. These may not be without interest and value, and it seems probable that an analyst, who is able to use the micromethod, will find it useful. A careful examination obtain evidences that will materially aid him in subsequent chemical analysis. Regarding the statements made by some that "the results of microscope examination are not always uniform," I must refer them to the non-conformity in results of analytical chemists in organic and even inorganic analyses, unless by practice the individual masters the difficulties. And again it has been recently said, "that in the case of the deterioration of vegetable drugs through atmospheric influences or age, as well as in the adulteration of a genuine with inferior drugs, the difficulty of determining with the microscope the respective content of change or admixture is almost insuperable." This may seem to be so, and while chemical analysis is necessary, still there are many cases where the quantitative determination of admixtures and adulterations, if they are to be determined, can be effected only by means of the microscope.

It would not be a hard matter to prepare a lengthy paper on the difficulties attendant upon research in this direction. Was there anything more difficult a few years ago than the study of bacteria? Not until Koch devised a convenient and comparatively easy method for this kind of investigation did this department, which to-day is recognised as a branch in science, become so popular. Even the medical student of the first and second year is taught to recognise and diagnose the insignificant Bacillus tuberculosus. As has been said before, this paper is but a preliminary one, and while I have been at work upon the subject for some time, the work has been done under rather disadvantageous circumstances, and it is presented at this meeting to elucidate a principle, and present the results of what may be an incomplete method, for your consideration. The method of procedure is as follows:—A measured quantity (about 200 Gm.) of substance is thoroughly mixed with a measured amount (2 or 3 C.c.) of water. One, two, or three drops formed on the finger of this mixture are placed in the slide and covered with a cover-glass. In the eye-piece of the microscope is slipped a piece of glass (corresponding to an ocular micrometer), containing 100 square Mm. By a little practice a slide may be prepared that is fairly uniform, or uniform places upon it may be selected. This being done, then a count is made of the number of starch grains, fibres, or characteristic tissue in the spurious substance, contained in 100 square Mm., and the same compared with a genuine sample. For instance, mixtures were made of genuine cloves with potato-starch, wheat-starch, cedar-wood, turmeric, and it was observed that quantitative relations by comparison do to some extent hold even in this crude way of procedure. In determining the oil a slightly different method was pursued.

A sample of pure potato-starch was examined and 100 (Mm.)² was found to contain (32 + 32 + 32 + 32) 127 starch grains. Another 100 (Mm.)² contained (32 + 32 + 32 + 32) 120 starch grains.

II. A sample of powdered cloves admixed with 50 per cent. of potato-starch yielded the following results.

<table>
<thead>
<tr>
<th>Grade</th>
<th>50.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>(14 + 15 + 12 + 15)</td>
<td>56 grains = 45-34 per cent.</td>
</tr>
<tr>
<td>(13 + 11 + 18 + 13)</td>
<td>55  = 44-53</td>
</tr>
<tr>
<td>(17 + 16 + 16 + 12)</td>
<td>62  = 50-20</td>
</tr>
</tbody>
</table>

III. A sample containing 30 per cent. of potato-starch:—

<table>
<thead>
<tr>
<th>Grade</th>
<th>29-14</th>
</tr>
</thead>
<tbody>
<tr>
<td>(10 + 10 + 11 + 11)</td>
<td>43 grains = 34-00 per cent.</td>
</tr>
<tr>
<td>(7 + 10 + 11 + 8)</td>
<td>36  = 29-14</td>
</tr>
</tbody>
</table>

IV. A sample containing 20 per cent. of potato-starch:—

<table>
<thead>
<tr>
<th>Grade</th>
<th>25-10</th>
</tr>
</thead>
<tbody>
<tr>
<td>(7 + 8 + 7 + 8)</td>
<td>30 grains = 24-25 per cent.</td>
</tr>
<tr>
<td>(7 + 6 + 9 + 9)</td>
<td>31  = 25-10</td>
</tr>
</tbody>
</table>

V. A sample containing 10 per cent. potato-starch:—

<table>
<thead>
<tr>
<th>Grade</th>
<th>8-90</th>
</tr>
</thead>
<tbody>
<tr>
<td>(4 + 2 + 3 + 2)</td>
<td>11 grains = 8-90 per cent.</td>
</tr>
</tbody>
</table>

VI. A sample of pure red cedar yielded the following:—

<table>
<thead>
<tr>
<th>Grade</th>
<th>8-10</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1)</td>
<td>7-1891 per cent.</td>
</tr>
<tr>
<td>(2)</td>
<td>9 = 24-25</td>
</tr>
<tr>
<td>(3)</td>
<td>8 = 21-60</td>
</tr>
</tbody>
</table>

VII. Cloves containing 20 per cent. red cedar yielded:—

<table>
<thead>
<tr>
<th>Grade</th>
<th>10-8</th>
</tr>
</thead>
<tbody>
<tr>
<td>(2)</td>
<td>3 = 8-10</td>
</tr>
</tbody>
</table>

All of the above results were obtained by using a 4-inch objective. In the examination of turmeric a 6-inch objective was used.

IX. Turmeric pure, using one part of water:

<table>
<thead>
<tr>
<th>Grade</th>
<th>118</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1)</td>
<td>(11 + 11 + 6 + 5) 23 grains.</td>
</tr>
<tr>
<td>(3)</td>
<td>(7 + 8 + 6 + 5) 26</td>
</tr>
<tr>
<td>Average</td>
<td>2 = 118</td>
</tr>
</tbody>
</table>

X. Cloves containing 10 per cent. turmeric, using 2 parts of water:—

<table>
<thead>
<tr>
<th>Grade</th>
<th>9-47</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1)</td>
<td>10 = 8-47 per cent.</td>
</tr>
<tr>
<td>(2)</td>
<td>11 = 9-32</td>
</tr>
<tr>
<td>(3)</td>
<td>10 = 8-47</td>
</tr>
</tbody>
</table>

While the above results show a variance, and one that is not constant in any one direction, still they are of some encouragement. Hoping that the possibilities of this kind of research was not limited to mechanical admixtures, the author experimented with the view of obtaining quantitative results upon the oil contained in cloves. For this purpose a small extractor, graduated to a mark, was made out of a piece of glass tubing. This was filled to the mark with cloves and exhausted with ether, the whole operation requiring about one minute. The ether containing the oil was allowed to drop in a watch crystal containing a few drops of alcoholic KOH solution, the potassium eugenol forming at once and the ether evaporating. To the residue was then added a known quantity (2-3 C.c.) of water, the mixture thoroughly stirred, and a drop of the liquid collected on the finger and used on the slide. 25 (Mm.)² were examined and the number of (Mm.)²—approximately—filled with crystals were counted.

XI. Pure sample of cloves:—

<table>
<thead>
<tr>
<th>Grade</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1)</td>
<td>8</td>
</tr>
<tr>
<td>(2)</td>
<td>6</td>
</tr>
<tr>
<td>Average</td>
<td>8</td>
</tr>
</tbody>
</table>

XII. Sample containing 50 per cent. of cloves of original sample contained:—

<table>
<thead>
<tr>
<th>Grade</th>
<th>11-45</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1)</td>
<td>8</td>
</tr>
<tr>
<td>(2)</td>
<td>3</td>
</tr>
<tr>
<td>Average</td>
<td>11 = 45 per cent. oil.</td>
</tr>
<tr>
<td>(3)</td>
<td>4</td>
</tr>
</tbody>
</table>

Three commercial samples were examined, one that was said to contain much allspice. An examination based on the "port wine" cells of allspice yielded the following results:—

XIII. Genuine allspice sample yielded:—

<table>
<thead>
<tr>
<th>Grade</th>
<th>20 &quot;port wine&quot; cells.</th>
</tr>
</thead>
<tbody>
<tr>
<td>(5 + 9 + 6 + 5)</td>
<td>20 &quot;port wine&quot; cells.</td>
</tr>
</tbody>
</table>

XIV. Commercial sample gave:—

<table>
<thead>
<tr>
<th>Grade</th>
<th>13 &quot;port wine&quot; cells = 65 per cent. allspice.</th>
</tr>
</thead>
<tbody>
<tr>
<td>(3 + 3 + 4 + 3)</td>
<td>13 &quot;port wine&quot; cells = 65 per cent. allspice.</td>
</tr>
</tbody>
</table>
A sample supposed to contain a large amount of wheat-starch yielded a surprisingly small amount comparatively, as was shown conclusively on comparing with pure mixtures of wheat-starch and cloves.

XV. Pure sample of wheat-starch contained:—
(59+6+67+89) 273 grains.

XVI. Sample of cloves containing 25 per cent. of wheat-starch:—
(16+19+16+18) 69=25.28 per cent.

XVII. Sample of cloves containing 10 per cent. of wheat-starch:—
(3+9+7+10) 39 grains =14.2 per cent.
(9+7+9+8) 38 grains = 120 per cent.

XVIII. Commercial samples, adulterated with wheat-starch:—

(1) 100(Mm.) = 18
(2) " = 24
(3) " = 26
(4) " = 24
4/94 = 28.26

The sample contained, therefore, 8.93 per cent. of wheat-starch, probably ten per cent.

XIX. Commercial sample with a slight clove odor. Under the microscope this revealed the presence of clove stems and starchy material. It yielded scarcely any potassium eugenol, but a green-coloured liquid to ether. This sample showed adulteration, and either an extraction of oil by distillation or loss of oil.

Anyone who has laboured with microscopical work for other than mere pleasure can readily comprehend the difficulties that must have been overcome by the author in this investigation thus far. And they who will attempt to corroborate these results or do original work in this direction must not be disappointed if results are not at once forthcoming. "Nature is taciturn, and one must wrench her secrets from her." But after these secrets are well obtained and the way discovered, the work is not so difficult.

The author hopes to elaborate upon the principles contained in this article, and that by similar methods, especially extraction and micro-chemical tests, the more important plant constituents even may be determined in a quantitave manner. Smaller squares than Mm. may be employed. Instead of tests being made upon a few milligrams of material, several grammes should be used to obtain more uniform results. It is believed that by preparing carefully a series of powders with the adulterants, fairly accurate results may be obtained—certainly sufficient to determine approximately the extent of adulteration without recourse to elaborate and prolonged chemical analyses. By employing the most accurate methods of sampling in use in the assay laboratory, samples must be obtained that are representative. Enlargements by photomicrography, and subsequent cutting out and comparing by weight the tissues printed and the parts remaining may be of service. Finally, much time must be yet devoted in ascertaining the real and permanent value of quantitative microscopical results to that of chemical results. It is hoped that many will pursue similar lines of research.

The Importance of the Study of Biochemistry. *

By M. A. de Schminke,
Washington, U.S.A.

When the controversy between the two schools of the vitalists and chemists as to the true cause of the diseases produced in animals by the inoculation of putrid organic matter was at its height, Panum, of Copenhagen, caused a careful investigation to be made into the substances extracted from putrid organic matter chemical substances which, when perfectly free from every form of germ life, produced intoxication and death. But, he said the poison extracted from this putrid matter is undoubtedly a pure chemical compound, it may, however, be produced by a microbe, and both microbe and poison play their part in the disease.

Now more than fifty years later, though the microbe's origin of most diseases has been thoroughly established, it has also been shown that the chemical products of these germs are the direct cause, in most instances, of the fatal effects. For example, in diphtheria, the growth of the germ is but a local manifestation, while the poison it produces is distributed throughout the whole system. Then, however, the germ has been discovered that is responsible for a disease or for other changes, to which we will presently refer, the door has but been opened for a study of the most interesting chemical problems that can be imagined. Germs in general are cells of protoplasm, and it is by a study of their actions and the changes which they produce that we can gain a better insight into the processes of life. Fortunately, the majority of germs can be easily cultivated artificially, so that it is not difficult to obtain solutions of their products, but it is difficult to isolate these products from the solution and determine their nature. For the most part, the substances produced by bacterial growth have been found to belong to two classes, the albuminoids and polymines, the latter corresponding closely in many of their properties and composition to the vegetable alkaloids. Our knowledge of the albuminoids, however, is very meagre. We can divide them into certain general classes, as 1. globulins; 2. albumooses (hem proteo or deutermino albumooses); 3. alkali or acid albumins; 4. peptones, etc.; but with this we have only made a step in the dark, as it has given no idea of the actual composition and the substances about which we speak, beyond that they contain carbon, hydrogen, oxygen, nitrogen, sulphur, and phosphorus, in certain proportions, and differ in coagulation. Do these apparent albuminoid substances from bacteria belong to the class of albumoses, or are they chemical dyes, or dyes, many of the reactions of which they show? Can they be proved to be dyes by their hydrating and digesting action, and shown to be allied to ptyalin, peptin, etc.? At first it was held, and is still held by some, that the presence of albuminoid matter was necessary to the growth of the germ, and that the products of the germ life were chemically quite different from the products of the albuminoid matter upon which they fed. But it has been proven too that some of the same substances are obtained by the simple action of acids and alkalies upon albuminoids, and it is often difficult to decide whether the albumoses and alkaloids have been produced by the alkaloid or the acid. To prove that this it is necessary to cultivate the germs upon solutions which do not contain a trace of albuminoid matter. This Fermi and Uschinsky have succeeded in doing with a number of different germs upon a solution of glycine and mineral salts (ammonium phosphate, and acid potassium phosphate), and I have also with the hog cholera, glanders, and recently tubercle bacilllus by the addition of arsenic to the above media. From these cultures albuminoid substances have been obtained as well as alkaloids, showing that they have truly been built up and elaborated by the germ, and are to be compared to intercellular secretions and excretions of these minute forms of life, and not to simple products of decomposition from albuminoid matter in solution. That the products formed under the different conditions are similar is shown by the same physiological action of malein prepared from these artificial cultures or from cultures upon beef broth. This power of the germ to multiply upon a solution of mineral salts where the carbon, hydrogen, nitrogen, and phosphorus are present in an easily assimilable form is not surprising, for we deal here with the lowest form of vegetable life, and it is well known that plants cannot live upon albuminoid matter directly, but only when by decomposition it has been reduced to its elementary condition.

The study of these products of the germ life has made but little progress so far as their actual chemical constitution is concerned. Much more attention has been paid to their physiological effect. It has been learned that some of these products will render an animal insensitive to the action of disease germs, but what the chemical change which can have taken place and caused this immunity may be, is one of the problems for the biochemists and physiologist to decide.

It has been found, too, that the blood serum of animals that have been made immune to disease has a germinidal action and will render other animals immune. Where does this property lie? What chemical change again has the blood undergone? In his studies upon the albuminoids of the egg, Scholl has indicated where this property may lie. He found that egg albumin exerted a germinidal effect, that this germinidal power was destroyed by heat and could be restored by treating the albumin with alkali. This was similar to some of Buchner's observations upon blood serum, where he found the bacteriolidal property could be restored by the use of an alkali. Scholl's theory for explaining this, and also at the same time the coagulation of albumin, is that the normal albumin has a composition corresponding to potassium carbonate, that upon heating carbon dioxide is given off and the albumin coagulated by the consolidation of two molecules, while when the alkali albumin is heated no decomposition will take place or coagulation of the albumin.

\[
\text{Albumin} \xrightarrow{\text{O}} \text{CO} + \begin{cases} \text{Albumin} \xrightarrow{\text{O}} \text{CO} \\ \text{K} \xrightarrow{\text{O}} \text{CO} \end{cases} \\
\text{equals} \quad \text{CO}_2 \xrightarrow{\text{K}_2\text{CO}_3} + \begin{cases} \text{Albmimn} \\ \text{Albmimn} \xrightarrow{\text{K}} \text{CO}_2 \end{cases} \\
\text{K} \xrightarrow{\text{2KOH}} \begin{cases} \text{H}_2\text{O} + \text{Albmimn} \xrightarrow{\text{OK}} \text{Albmimn} \xrightarrow{\text{O}} \text{CO}_2 \end{cases}
\]

The carbon dioxide in the albumin is also set free by acid in the cold, which will explain the coagulation of albumin by acid. In the albumin molecule, then, there is a group of atoms with a bacteriolidal action, which group is destroyed by heat and restored by alkali, just as there are certain groupings necessary for the production of a disinfector, or rather just as the disinfectants are characterised by certain groups. The confirmation of these experiments will open up a field of enormous possibilities, as sulphur is an element.

* Read at the Baltimore meeting, December 28, 1893.
which in many cases can replace oxygen, and the re-
sulting compounds would be very interesting, as well
as lead to a number of new products, and, eventually,
to a better understanding of the albuminoid mole-
cule.
As just mentioned, it has been found that in the
case of a great many diseases, animals can be made
insusceptible by vaccination, and that the blood
such in those animals will make others immune to
each. But this immunity only holds for the particular disease
against which the animal was first vaccinated, and
does not protect the animal against another disease.
A guine pig can be protected from a hog cholera
inoculation by an injection of the albuminoid product
extracted from the cultures. The same pig will die
if inoculated with swine plague. If, however, it be
vaccinated both for hog cholera and swine plague,
with the products extracted from their respective cul-
tures, the animal will be insusceptible to both diseases.
Just in the same way in each particular disease some
chemical change is produced in the blood or tissues,
and the work of the chemist should be to find out what
these changes are. The possibilities are enormous,
the difficulties many, but by careful study, accom-
panied necessarily with a certain amount of bacterio-
logical work and the observation of pathological changes,
we can, I hope, arrive at a more definite understand-
ing of the processes of life.
It is, however, not only with reference to diseases
that a study of biochemistry is important. From a
practical and commercial standpoint the work is use-
ful. J. A. Davalos, of Havana,* describes the isolation
of a distinct ferment and a number of bacilli from
different tobacco leaves, some of which in artificial
culture give distinct poisons. The different varieties
of tobacco show different germs. These germs, by
their growth upon the tobacco, give to it its peculiar
flavour and odour, and the different qualities of to-
bacco owe their value to some particular ferment.
As I have noticed, a bright yellow American high grade
tobacco shows the presence of a germ altogether
different, producing different substances from that of
a low grade tobacco. Therefore, if the germs of a
low grade tobacco can be destroyed and those from a
fine tobacco substituted, we should be able to greatly
improve the manufactured article. Now in practice,
better foreign tobacco is often mixed with lower grade tobacco to improve
the quality. The manufacturer has learned by experience to make
use of the different germs of the tobacco. But the
chemist should not stop here. He should find out
what the products of the growth of these germs are.
This is possible, because they can be isolated, cultivated,
and the product of each individual germ determined, and eventually its identification or syn-
thetic preparation.
Again, in Denmark, the practical manufacture of
butter and cheese has been greatly advanced by the
use of butter ferments, as they have been called. The
flavour and aroma of butter and cheese are due to the products of a particular bacterium, or of several forms.
Now these can and have been isolated, and to produce
the best butter and cheese only those bacteria are used
upon sterilised milk which give a desirable flavour,
while normally those with undesirable products would
not be used therefor. With characteristic ferment in
butter and cheese. Here again the products of the
growth of these bacteria should be studied, which in
many instances would no doubt be found to be sub-
estances of easy synthetic preparation. It would be
very much better to be able to add to a butter or cheese the exact element which will impart a special flavour, rather than to have to inoculate
the cheese and milk with a particular bacterium or mix-
ture of bacteria for a desired quality. As has been
well stated, we may see the time when each dairy
is provided with a bacteria farm, and each particular
brand of butter and cheese will have its corresponding
originator, labelled and reared with as much care as is
given to the cow from which the milk is obtained.
In their relation to the soil and plant life, the germs
and their products are invaluable. Warington
and Winogradsky, in their isolation of the nitrifying
organisms which convert nitrogenous matter into
nitrates and nitrates, have thrown great light on the
absorption of nitrogen by plants. Recently, Win-
ogradsky has described an organism which converts
the nitrogen of the air directly into nitrates. Again, there
are a number of germs that are ordinarily found in
water or the soil, which will reduce nitrates to nitrites
or ammonia, as well as some pathogenic germs usually
present in the soil, which will flourish in artificial
media in an atmosphere of nitrogen. We know that a
subsoil, freshly turned, will not be productive until it
has been exposed for some length of time to the air
and moisture, and to the action of the germs of the
air. The plant does not take up directly in the form
in which it exists in the soil, the mineral matter that
it needs for its growth, but only when that is
modified to a simpler form by the processes of life.
Phosphorus is one of the elements which, whether
combined in albuminoids or mineral salts, seems
to be necessary for the growth of the germ, and is
also necessary for the life of plants. By closely
following the gradual changes in the artificial cultures
of germs, we can arrive at a more definite understand-
ing of the assimilation of mineral matter by the
plant, as well as the fixation of carbon, the formation
of starch and sugar, and possibly also, as has been
suggested, of the building up of aldehydes.
I have only mentioned a few of the many directions
in which a conjoint study of bacteriology and their pro-
ducts are important, with the desire of emphasizing
the interest attaching to such investigations. It is
along this line of research that the solution of many
of the problems of life that have been a puzzle to both
physiologist and chemist undoubtedly lies.

No. 18.

PROCEEDINGS UNDER THE
PHARMACY ACTS.

SALE OF POISON BY AN UNREGISTERED PERSON.

At the Sheriff Court, Glasgow, on September 23,
before Sheriff Spens, John Taylor, 173, Slatebed
Street, Glasgow, was charged at the instance of
Richard Bremridge, Registrar to the Pharmaceutical
Society, with having contravened the 1st and 15th
sections of the Pharmacy Act, 1868. On May 27, 1894, he,—not being a duly registered phar-
macological chemist or chemist and druggist within
the meaning of the said recited Act,—within premises
at 248, London Road, Glasgow, then occupied by
William Nicol, unlawfully and contrary to the 1st
and 15th sections of the said Act, did sell to, named
Cottingham, son of, and residing with the now deceased,
Andrew Cottingham, 60, Barrowfield Street, Glasgow, a
quantity of Laudanum,—a preparation of opium, and a
poison within the meaning of the said recited Act,—
whereby the said John Taylor became liable in the
penalty of £5.
Mr. T. B. Morison, advocate, Edinburgh, appeared for the prosecution.

Mr. Matthew Walker, writer, Hamilton, appeared for the respondent.

The Lord Justice having been read over to the accused, he pleaded guilty thereto.

Mr. Walker, addressing the court, said: "The accused is an assistant in the shop, 248, London Road, and the William Nicol mentioned in the complaint is a duly qualified chemist and druggist. The accused was in charge of the shop on Sunday evening, May 27, last, and during the closing time when a boy presented himself and requested to be supplied with 4d. worth of laudanum. The accused sent the boy home to ask what was the purpose of the medicine, and he returned shortly afterwards and made the statement that it was to be applied to his father's head, outwardly as the accused understood it. The medicine was then supplied, the accused first of all putting two labels on the bottle, one marked "poison" in red letters. It is hardly necessary to say that the same circumstances would have occurred had William Nicol been present. He happened to be absent on that evening, but the same thing would have taken place, with the same result. The accused, took the caution to send the boy home to ask the purpose of the medicine. The accused has been nine years at the trade, and has passed one of the examinations necessary to qualify him, and in the circumstances I ask your Lordship to impose a nominal penalty.

Mr. Morison said: I appear for the Registrar to the Pharmaceutical Society, and I think this is a very serious case, and one typical of the dangers to which the public are exposed if poisons are sold by unqualified men. The facts of the case have not been fully brought before your Lordship, and in one respect my information differs very materially from that which was presented by my learned friend, because the facts as I understand are, that this boy Cottingham, who is only eight years of age, went to the shop and asked for 4d. worth of laudanum. That I may explain is a large quantity, and contains several fatal doses. It is true the accused at first declined to sell the poison, and asked what purpose it was for. The boy Cottingham returned to his father, and his account is that he came back to the shop and said it was for killing vermin, and on that statement he says he received the poison. No registered chemist would supply poison in that quantity to a boy eight years of age, and certainly no one connected with the sale of laudanum would supply it upon the statement that it was for killing vermin. I think also that this is a very serious case in this respect, that from the history of the facts which were brought out by the Procurator Fiscal, who sent the papers to the Registrar with the view of prosecution —

Sheriff Spens: The father drank it, did he?

Mr. Morison: Yes. The next serious stage in the case is that this boy's father is found lying dead with the bottle of laudanum at his bedside. Whether he took the poison with a suicidal intention or by misadventure is probably unknown, but at all events it is certain that this boy's father died from the effects of the laudanum which was purchased in this very slipshod way. Now the Act was passed to prevent cases of this kind, and it requires that no person shall sell the poison, even although he may be assisting a registered chemist, unless the person actually conducting the sale has the necessary qualification, that is to say, he is registered, and he is acquainted with the properties of poisons. Of course anything may happen if poisons are to be sold in this way.

Sheriff Spens: Is there any clause in the Act with reference to the sale of poisons to children?

Mr. Morison: No, there is no special provision in regard to that.

Sheriff Spens: You mean it may be sold to a child of three, four, five, six, seven or eight years of age?

Mr. Morison: I think it is the practice of registered chemists never to sell poisons to children at all. What they do is, they send the child home and say they must have an older person with them. I understand that is the registered chemist's practice.

Sheriff Spens: There is no provision for it?

Mr. Morison: There is no provision for it, but all the penalty that can be imposed under the fifteenth section is a penalty of £5, and I would move for the circumstances that the full penalty be imposed. It was not a case of breach of the Statute in ignorance; the man knew perfectly well he was contravening an Act of Parliament which was passed for the safety of the public, and in moving for the full penalty, I also ask for costs. The provision is that the penalty to be recovered is a sum of £5, meaning, I understand, that the full penalty is to be imposed in every case; although sometimes the penalty is modified, but I think this is not a case where modification should be made.

Sheriff Spens: Does it say "not exceeding £5"?

Mr. Morison: No, it is £5; and in England it is the practice for the full penalty of £5 always to be imposed; but, of course, this is a prosecution under the Summary Procedure Act, and your Lordship has power under that Act to modify the penalty.

Sheriff Spens: I am not so sure of that. The Summary Procedure Act is merely the procedure in applying this Act. I think the penalty must be £5.

Mr. Morison: Well, my Lord, I cannot argue it is so, that is our view, but we have never pressed it so in the court.

Sheriff Spens: What are the words of the Summary Procedure Act?

Mr. Morison: We have always felt the difficulty of the point, and we have never raised it. While we cannot say your Lordship has not power to modify the penalty, I move for the full penalty in this case on account of the flagrant breach which was committed by the accused.

Sheriff Spens: I doubt if there is any power, but I do not see why should not impose the full penalty.

Mr. Walker: I do not know how far it is fair to connect accused with this suicide?

Sheriff Spens: That has nothing to do with it. The Pharmacy Act provides that no unqualified man shall sell poisons and I do not think any such sale should have taken place to this child.

Mr. Walker: Of course the accused's story of the message brought back to him differs from that of the prosecution.

Sheriff Spens: My own view is that the Summary Procedure Act does not affect the penalty. The words of the Pharmacy Act are that he is liable to a penalty, the Summary Procedure Act only affects the procedure.

Mr. Walker: I was assuming, of course, that your Lordship has power to modify the penalty.

Sheriff Spens: Even if I had, I do not think I would be inclined to do it here.

Mr. Morison: I move also for the costs.

Sheriff Spens: What do they come to?

Mr. Morison: £2 1s. 8d. I understand.

Sheriff Spens: Well, I will say £2. Are the expenses to be paid just now?

Mr. Walker: Yes.

Sheriff Spens: I will say "in respect that the penalty and expenses are paid at the bar, I find it unnecessary to make any further order with regard to the recovery thereof."

The fine and costs were then paid.
PROSECUTIONS BY THE INLAND REVENUE AUTHORITIES.

ALCOHOL IN TEMPERANCE DRINKS.
A case of considerable importance to manufacturers and sellers of "non-intoxicating" liquors came on for hearing at the Lancaster County Petty Sessions on Saturday, when James Warwood, shopkeeper, Morecambe, was summoned at the instance of the Excise authorities for selling alcoholic liquors without a licence. Mr. Lees, of Sommerley House, prosecutor, said the action was brought under the Act of William IV., the penalties sought to be recovered being £10. It was the first case of the kind brought by the Commissioners of Inland Revenue, and they had been induced to take proceedings because the manufacture and sale of these so-called temperance beverages—such as hop ale and herb beer—were largely on the increase in the neighbourhood. The object was to make manufacturers more careful to keep within the limit allowed by law, viz., two per cent. of alcohol. Defendant was a shopkeeper, and also had a stall on the promenade, where he sold hop ale, herb beer, and similar commodities. On August 3, Mr. Eaton, supervisor, purchased from him a bottle of hop ale and two bottles of herb beer for the purposes of analysis. They were analysed at Somerset House, and in one case the proportion of alcohol or proof spirit was found to be 2:4 per cent., in another case 4:34 per cent., and in a third case 2:3 per cent. Samples of this kind of drinks had been taken which showed that in some cases they contained from 8 to 10 per cent. of proof spirit, whilst the strength of good ordinary beer was from 7 to 8 per cent., so that not only was there an evasion of the law, but these beverages were foisted upon the public as temperance drinks when they really contained more alcohol than ordinary beer. In the course of the case it was remarked that the liquor been drunk instead of sent for analysis, the penalty would have been £25 instead of £10. Mr. Eaton said he had warned defendant and all the sellers of these drinks that they contained alcohol, but no notice was taken of the warning, and therefore these proceedings were instituted. Mr. Tilly, for the defence, said Mr. Warwood was innocent of any intention to evade the law. He bought the beverages direct from the manufacturer, and sold them as he bought them, but however, impossible to manufacture these beverages without alcohol, because the process of fermentation, which was one of the elements of their manufacture, produced alcohol. Mr. Alpe pointed out that it was possible to make these drinks without alcohol, and stated that one well-known temperance "super-" contains only 1 per cent. of alcohol. The Chairman (Mr. E. B. Dawson) said defendant had not intentionally done wrong, but these drinks were foisted upon the public as non-intoxicants, and no doubt hundreds of people were deluded. A fine of 10s. and costs was imposed.—Yorkshire Post.

THE SALE OF MEDICINES UNSTAMPED.
James Ockenden, chemist, 18, Moorfields, appeared at the Mansion House, before Mr. Alderman Samuel, on September 24, upon four summonses for selling tinctures of belladonna, aconite, and nux vomica, and enunciating which the vendor called the curative secret of the art. Revenue stamps required by the Medicines Stamps Act, 52 Geo. III., cap. 150, sec. 2. Mr. Dennis appeared for the Inland Revenue, and Mr. Lewis Thomas represented the defendant. In opening the case, Mr. Dennis said stamps were required on all medicines in which the vendor claimed the curative secret of the art. Necessary in the preparation of the same, or which were manufactured under Letters Patent. The third category of medicines in regard to which stamps were required was the one relied on in this case—namely, medicines which were held out by notice or advertisement as being beneficial for the relief or cure of disease. Evidence was given of the purchase of the tinctures, which were contained in a half-crowns case of homeopathic medicines, purchased from the defendant. Mr. Lewis Thomas said the tinctures had been in the public for the last ten years, without any interference from the Inland Revenue authorities, who were consulted before they were offered for sale at all, and who, on the authority of Sir John Bridge, decided at that time that no stamp was necessary. He submitted that these tinctures were not held out in the handbills enclosed in the box as nostrums or as specious for the prevention or cure of disease. The Alderman: But there are the recommendations in the handbill headed "The Preservation of Health and Restoration to Health." Mr. Lewis Thomas: If you were to tell a man to put his head under a pump, as it was good for health. The Alderman: The Inland Revenue would say that the pump must have a stamp on it. Mr. Lewis Thomas: But the pump could not be held to be a tincture or nostrum. He further submitted that the sale of the tinctures came within the two exemptions allowed by the Act, namely, where the drugs were enter in or moved entire and without admixture, or where they were sold by a person licensed to sell medicines chargeable with the stamp duty. The Alderman: In the Act the words "and having the labels properly stamped" follow the words you have read. Mr. Dennis: The burden of proving that the drugs were entire is on the defendant, and as a fact the word tincture implied that the drug was a spirituous compound. Evidence was then given as to the purchase of the eucalyptus pastilles. Mr. Thomas thought this was a very vexatious summons, as the Tasmanian Eucalyptus Oil Company, who manufactured the pastilles, had been in communication with the Inland Revenue Department, and on finding that a stamp was required, had called in the issue of boxes for the purpose of having them stamped. The Alderman said the defendant in that instance might be a victim; but it was a very flagrant case, and he should impose the full penalty of £30. For selling the tinctures the defendant was fined in each case a fine of 20s. and costs. It was stated that the total amount of fines and costs was £13 16s. Mr. Lewis Thomas intimated that there might be an appeal.—Daily Graphic.

PROCEDINGS UNDER THE SALE OF FOOD AND DRUGS ACTS.

DEFICIENT TINCTURE OF RHUBARB.
At the Saddleworth Police Court on Wednesday, September 12, before Mr. B. H. Howell, magistrates, Albert Ashworth, general dealer, Greenfield, was summoned for a breach of the Food and Drugs Act. Mr. A. L. Bridge, who until recently has acted as the County Council analyst, prosecuted, and Mr. Innes, of Stalybridge, conducted the defence. Mr. Bridge alleged that on September 9, the defendant, without the consent of the analyst, purchased and purchased two tinctures of rhubarb, for which he paid sixpence. He then told the analyst that he was at work for analysis, and the tincture was divided into three parts in the usual way. One part was sent to Mr. Allen, the county analyst, who had since sent the following certificate: "I am of opinion that the sample received is a genuine extract of rhubarb, absolute alcohol 24:19, water 73:21. The sample contained only one half the amount of extractive matter
naturally to genuine tincture of rhubarb of good quality, and but little more than one half the amount of alcohol which is prescribed by the British Pharmacopoeia to be used in its preparation; in addition to this the sample was free of saffron, which is directed by the British Pharmacopoeia to be used in the preparation of tincture of rhubarb in the proportion of a quarter of an ounce to a pint. Mr. Innes questioned Mr. Bridge as to whether the spirit and the saffron might not have disappeared through the bottle being repeatedly unsealed and exposed to the light, and Mr. Bridge maintained that the difficulty and difference would thus have been made to the tincture. Mr. Innes said he had authority for saying that Mr. Bridge was wrong. Mr. Innes had three lines of defence. In the first place, he contended that the summons was bad, inasmuch as it had not been taken out within twenty-eight days; in the second the defendant was exonerated, because on the bottle purchased from the wholesale dealer there were the words: "warranted genuine;" and in the third he maintained that the spirit and the saffron had evaporated, and the defendant was not liable. The bottle of tincture of rhubarb was purchased ten years and a half ago, and they could not be surprised if a change in its composition had taken place. As regards the saffron, it was of small account if it had disappeared, as it was only used for colouring purposes. Mr. Bridge said the saffron had medicinal qualities. When the magistrates, on the advice of their clerk, decided against him on the two first points, Mr. Innes called defendant and his wife to prove that the tincture was purchased over ten years ago, and had never had water added to it. A fine of 5s., including costs, was imposed. The magistrates considered that the defendant had broken the law unknowingly.—*Oldham Chronicle.*

**POISONING CASES AND INQUESTS.**

**POISONED BY CARBOLIC ACID.**

Mr. Coroner Ivenon and a jury held an inquest at Gainstrop, on September 18, as to the death of a Gainstrop hotel-keeper named John Brook, aged 45. Deceased said that on the evening of the day he died he had taken out of a bottle kept in the house. His wife heard him call and called a neighbour, who gave what assistance he could, but death speedily took place. Police-constable Holliday said the previous night just after 11 o'clock he went to the house of the deceased and found him lying on his back on the floor quite dead. He found a blue-coloured bottle empty, but smelling strongly of carbolic acid, and labelled so. There were two tumbler glasses on the table, one containing water and the other a small portion of carbolic acid, of which the room smelt strongly. Dr. Wright stated that he was called in to see the deceased, and found him dead, and carbolic acid had caused corrosions on each side of the chin and throat, death having resulted from poisoning by that agent. Deceased had been "very unlucky" in business, and had drunk heavily. He filed his petition some seven months ago. It was shown that the brandy bottle was kept in the small cupboard as the carbolic acid, and a verdict of "Death by misadventure" was returned.—*Sheffield Independent.*

**CHILD POISONED BY SWEETEN STRUYP.**

The Bolton Borough Coroner, Mr. R. Taylor, held an inquest at the Victory Hotel, on September 21, respecting the death of Thomas Slatter Booth, thirteen months old, of 22, Victoria Grove, which occurred on Wednesday. Elizabeth Booth said deceased had recently been troubled with his teeth and restlessness. On Tuesday night she administered a teaspoonful of Hamer's infant preservative in accordance with the directions. She had previously used it for the same child occasionally without evil results. The following morning deceased seemed very unwell, and Dr. Garstang was summoned and attended up to death taking place. Dr. Garstang deposed to visiting deceased and finding him in a comatose condition. The pupils of the eye were intensely contracted, the surface of the body pale, there was some cold perspiration, and the child was breathing slowly. It was with great difficulty that it could be awakened, and it immediately relapsed into the original condition. These symptoms coincided with opium poisoning. On questioning the mother she explained that she had given the child some soothing syrup. In witness's opinion death was due to opium poisoning acting on an enfeebled constitution. On a healthier child a similar dose would probably not have had a similar effect. The Coroner: That shows the folly of labels advising a certain quantity to be administered to every child between specified ages. Dr. Garstang considered that opiates ought not to be given in any form except under medical advice. The Coroner endorsed this view of the matter. It was undoubtedly a common practice, and there was nothing to prevent the sale of it at present. It was the first inquest he had held under such circumstances. Poor people could not afford to rush to a doctor every time, but they thought if they asked for a small quantity should be given, and that diluted. Ultimately the following verdict was returned, in accordance with medical testimony: "That deceased died through opium poisoning, acting on a previously enfeebled constitution, and administered inadvertently by the mother."—*Bolton Journal.*

**ACCIDENTALLY POISONED BY CARBOLIC ACID.**

The Coroner of the Mid Division of Oxfordshire, Mr. W. W. Robinson, held an inquest on September 24 on the body of Arthur Machen, aged 43, a retired farmer, who died from the effects of drinking carbolic acid. The inquiry took place at the residence of the deceased at Shotover Hill, a short distance from Oxford. The deceased instructed that on the previous evening he accompanied her husband to Beawley, where he went in order to take a farm. They returned home on Thursday evening. At her request her husband went into the kitchen for some water. He called out "I have done something." or "I have done it; run and get some one." She asked him what he had done, and all he replied was, "Carbolic acid; run and get some one." She went for assistance, and he followed her. They went to a neighbour's house, which was within a short distance. He was laid on a sofa, and emetics were administered. A doctor was sent for, but her husband expired a few minutes before he arrived. The bottle of carbolic acid was kept on the chimney-piece in the kitchen, and was used for sanitary purposes. A medicine bottle was also kept on the mantelpiece. The jury returned a verdict of death from misadventure.—*Daily Chronicle.*

**DEATH FROM OBERDOSE OF LAUDANUM.**

On Saturday, September 22, a woman named Jane Calder, residing at 15, Saunders Street, Edinburgh, was brought to the Royal Infirmary suffering from the effects of poisoning by laudanum. She did not survive her admission to the institution, dying early on the Saturday morning. It seems that the unfortunate woman, feeling ill, had taken some laudanum to relieve a pain in the side—the dose being, as the result proved, excessive.—*Scottman.*
PATENTS FOR MEDICINAL PREPARATIONS.

Complete Specifications Accepted.

No. 12.786.—August 4, 1894.—Frederick William Fletcher, Beauchamp Lodge, Enfield. Improvements in cinchona preparations, consisting in the use of hydrobromic acid as a solvent for the extraction of the alkaloids and other active principles of cinchona bark, and the production thereby of improved preparations containing in perfect solution the whole of the constituents of the bark in intimate association with bromine, and capable of being taken without ill effects by persons in whom cinchona bark and its preparations have hitherto produced unpleasant symptoms.

No. 21.927.—August 11, 1894.—Dr. Edwin Klebe, of 8, Jahn Strasse, Karlsruhe, Berlin. Production of a medical preparation (antiphtlisin) for use in tuberculosis, from the tubercle bacillus, and the process employed therefor, consisting in the addition of an equal to the tubercle culture fluid, filtering, adding sodium bismuth iodide in excess, then soda lye, again filtering, and finally precipitating "antiphtlisin" from the fluid by the addition of alcohol.

No. 13.496.—August 18, 1894.—Emma Hopkins and Elizabeth Frost, both of Windsor Road, Slough, Buckinghamshire. An ointment for gatherings, abscesses (?), witlows (?), etc., consisting mainly or wholly of an extract of "lady" thistles, lard, and beeswax.

REVIEWS AND NOTICES OF BOOKS.

Dr. Pavy's views on diabetes are so well known that when, in his recent lectures at the Royal College of Physicians, he promised us a new departure, the general interest was keen indeed. What the new departure is he tells us in a work of about 300 pages, full of detail and matter. We cannot attempt to give a complete review or abstract of the book. Dr. Pavy assures the validity of the doctrine of the glycogenic function of the liver, according to which carbohyd- rates are stored up in the liver as glycogen, ready to be converted into sugar in a position to be utilised within the system. He shows (1) that the liver during life is not in a more saccharine condition than other organs. Sugar exists as a normal constituent of all the tissues and organs of the body. After death glucose is found in the liver, during life, however, a different sugar with a cupric oxide reducing power below that of glucose—in fact, the same sugar as is found in other structures. (2) The blood flowing from the liver does not contain more sugar than that flowing to it. Sugar is found equally distributed throughout the circulation, arterial, portal, or venous. After fasting, the portal blood contains as much sugar as other parts of the circulation. After the ingestion of carbohydrates it contains much more. This shows that sugar does not disappear in the capillary areas, and that there is no evidence that sugar is supplied constantly from the liver to the systemic capillaries, so that the liver exerts a check on the progress of the carbohydrate into the systemic circulation. This it does by converting the sugar carried to it by the portal vein into glycogen. In this Dr. Pavy agrees with others, but as further. The general belief hitherto adhered to is that the stored up glycogen is subsequently converted into sugar, and gradually and slowly given out in this form. This view is severely criticised, and the following objections are raised:—(1) In a rabbit the stomach is never empty, and in the portal blood, therefore, is always more sugar than in the systemic blood, which excess must be constantly checked by the liver. As Dr. Pavy says, "A state constantly calling for the exercise of a stoppage action is not reconcilable with stoppage for temporary storage." (2) Healthy urine contains sugar, which varies in amount with that of the blood of the general circulation. Both the blood of the general circulation and the urine remain uninfuenced by the injection of carbohydrates into the body so long as it does not exceed ordinary limits, so that in an animal like the rabbit, a vegetable feeder, we ought to have a constant storage by the liver (according to the older view). But can such a process of storage be carried on indefinitely? In fact, one is compelled to admit that ingested carbohydrates have no effect on the urine, because the amount of sugar in blood and urine remains unaltered, whether the animal is feeding or fasting.

The liver, therefore, does not store up carbohydrate as glycogen for subsequent discharge as sugar into the general circulation—it keeps the blood free from sugar and prevents the sugar of digestion—brought to it by the portal blood—from passing on. In diabetes we would have then a failure of the checking action of the liver, and the symptoms of the disease are due to sugar being allowed to reach the general circulation, so that those would depend (a) upon the extent to which this checking action of the liver is impaired, and (b) upon the amount of carbohydrates ingested. In severe cases of diabetes where sugar is excreted apart from food, we have a splitting up of the "glucoside proteins." Dr. Pavy, as the outcome of many experiments and analyses, argues that proteins are "glucosides," and this is the "newest" departure and a conception which must have created much surprise when first put in words. Analytically, he showed that out of proteins a cupric oxide reducing substance is readily separated, the source of which, it is argued, lies in the disruption or cleavage of the protein molecule itself on the following grounds: (a) the amount of cupric reducing substance obtained varies with the strength and the length of time of contact with the caustic potash used for solution of the albuminous material tested. Had there been free glycogen or starch, the amount would not have varied in this manner. (b) On treating egg albumin with water at a temperature of 150° C., unmistakable evidence of cupric oxide reducing products was obtained. (c) On appropriately treating egg albumin with caustic potash and alcohol precipitation, a substance is
obtained resembling Landwehr’s “animal gum,” which on treatment with sulphuric acid responds to the copper test, and with phenylhydrizin needle crystals of glucosezone is diffusible, therein differing from the amylose carbohydrates. This substance, which is not glucose, gives all the characteristic sugar reactions, and sugar Dr. Pavy does call it. It is not fermentable, and causes hardly any rotation with the polarimeter (0°–1 levorotation), per se not objections of great weight. (d) The sugar can be separated with sulphuric acid alone without previously boiling the albumin with caustic potash. Various forms of oeszone crystals are then obtained with phenylhydrizin, depending on the amount and duration of heat used during the process. (e) From the oeszone the sugar could be recovered by Fischer’s process. (e) Proteolytic ferments (pepsin) will set free the carbohydrate constituent of the proteid molecule in the form of sugar, as shown by the oeszone test. Theoretical considerations have further convinced Dr. Pavy of the correctness of his view. He alludes to the yeast plant, which uses up carbohydrates to build up its proteids, and “it is recognised by vegetable physiologists that asparagine, by combination with carbohydrate matter and the sulphur of a sulphur-containing body, is extensively concerned in the formation of proteid,” and it further seems probable “that proteid plays a participating part in the process of deposition of carbohydrate as a fabric and as a store material.”

We must therefore regard proteid matter as a distinct source of carbohydrate, and a part of the carbohydrate is used up in the formation of proteid and fat. Carbohydrate, reaching the liver as sugar, under the influence of living protoplasma, is (1) changed by dehydoration into glycogen. When glucose is injected into an animal it does not reappear as such, but in a form possessed of a lower cupric oxide reducing power, while in diabetes the urine ordinarily contains glucose. (2) The carbohydrate is utilised in the production of proteid matter (3) and also transformed into fat mainly in the intestinal tract, the villi being the seat of fat production from carbohydrate, while the liver plays but a supplementary part in the process, producing fat from the carbohydrate which escapes the villi and reaches the portal vein as sugar. Dr. Pavy surmises that the process of transformation is not a direct one, but one in which the production of proteid plays an important part. “The protoplastic matter of the cells of the villi may first lead to the incorporation of the carbohydrate into proteid, from which, by cleavage, the fat may be afterwards thrown off,” just as in the formation of adipose tissue, the protoplasma of the connective tissue splits off fat, and as the fat elements of the milk are derived by a process of splitting up from the mammary epithelial cells. Summing up, Dr. Pavy says “protoplastic action is the agency by which the appropriation of carbohydrate matter is effected, and the agents of appropriation are the cells of the villi and of the liver. Under normal circumstances carbohydrate is not allowed to pass these lines of stoppage. Conditions leading to its doing so occasion saccharine urine, which stands proportionate in extent to the amount of carbohydrate that escapes arrest, and is thus permitted to reach the general circulation.” We see then that there is much new matter in this work of patient labour and research. It is full of suggestions, and will no doubt have to run the gauntlet of severe criticism. Any real chemical advance in our knowledge of the constitution of proteids is welcome and desirable, and here we seem to have a great step in this direction. It is to be regretted that the style is often so elaborate and heavy that many passages are almost unintelligible on first reading them—a great drawback where the subject in itself is one requiring the closest attention.

The wealth of material for clinical study afforded by the various London hospitals is scattered over so wide an area, that in spite of the activity of medical journals and medical societies, whose published transactions contain numerous papers and recorded observations, much invaluable knowledge is lost to the world for want of adequate organisation. The larger medical schools publish annual reports, which not only constitute invaluable archives, but also reflect in varying degree the spirit of the individual schools. The editing of the present volume has entailed more than usual labour, since it includes a useful condensed general index to the whole series of fifty volumes. This index enables us to recall the great minds whose professional activity was centred in the Institution founded by the eccentric philanthropist whose name it perpetuates. The earliest volumes contain many contributions by Thomas Addison and Richard Bright, great physicians whom men now near the seventies remember as friends and consummate practitioners of the healing art, and whom the world acknowledges as giants in medical science. Later such names as William Gull, Hilton, Fegge, and Walter Monon appear to show that Addison and Bright left worthy successors, who have now, like their teachers, passed away. And, if it were needed, the present volume affords ample evidence that the spirit of these great men still lives in the workers who now occupy their place. Dr. Wilks contributes a paper relating the first case of aneurism treated by pressure, and so recalls to memory a great surgeon, Aston Key.

Mr. Jacobson, one of the editors, deals ably with one of the many dangers incurred by medical men in an article on primary syphilitic sores on the hands. Drs. Shaw and Perry contribute an exhaustive treatise on diseases of the duodenum, and among other articles is one by Dr. Bryant on hyperpyrexia, in which the guiding hand of Dr. Hale White, the other editor, can be traced, and Dr. White contributes a paper on diabetes mellitus. Mr. Targett has an article on a parasitic affection—hydatid of bone, and Mr. Gowland Hopkins one on some of the anatomical and physiological effects of a somewhat rare and very fatal disease, pernicious anaemia, the cause of which is still
unknown. Dr. Savage has a paper on suicide, Dr. Goodhart one on heart disease, Mr. Tabby on spinal disease, and Dr. Goodhall on hemorrhagic diphtheria and scarlet fever. Mr. Higgin's has a paper on distension of the frontal sinus.

Dr. Stevenson relates a case of especial interest to pharmacists—a case of poisoning by terchloride of gold. A boy had opened and sucked a tube, containing that substance, found by one of his playmates on a dust-heap, where it had found its way probably from some photographer's workshop. He was admitted in a state of collapse on October 22, and discharged quite well on November 4. The chief symptoms were vomiting, thirst, and diarrhoea. There were purple-black stains about the mouth, and gold was found in the vomit and feces, but not in the urine. The immediate treatment consisted in the exhibition of white of egg and milk, and in the application of warmth. The vomiting ceased on the first day, and on the second the patient was fairly recovered.

The volume is full of interest to medical men. It is well worthy of its predecessors, and of the great traditions of Guy's Hospital.

Correspondence.

A Soap Basis for Liniments.

Sir,—My paper on "A Soap Basis for Liniments" being taken as read at the Conference Meeting, I had not the opportunity of verbally commenting on the sample of lim. iodi submitted. The action of the alkaline olesates, etc., of the soap on the iodine has the effect of completely decolourising the preparation, which is a brownish-yellow when first made, rendering it snow-white in a few days. This may be due in part to the formation of hypoidote of soda, which, I think, would scarcely affect the usefulness of the liniment as an absorbent application, hypoidotes having been found effectual per se, but of this others must be left to judge.

285, Oxford Street, W.

E. W. Lucas.

The Revision of the British Pharmacopoeia.

Sir,—Mr. Peter Boa asks me to prepare a sample of ung. rigorous by my method and let it finish off itself—his method—and he hints that then I should be in a better position to judge of and report on the view he takes of the subject. I say that I should certainly require at least six months to bring such an experiment to a satisfactory issue, and that I have in hand many a little job that leads along the flowery way of hope and faith, whilst his would, to my way of thinking, lead along the thorny by-path of doubt and trepidation, I think he will pardon me for not accepting the challenge. Last year about this time we did prepare certain ointments with the view of testing their keeping qualities. One or two of them still escape Time's ordeal, and seem quite presentable. Amongst these is ung. rigorous, a sample of which I take the liberty of sending you, together with a few more of my pets of later production for your kind inspection. Until the last two or three years we could not get ung. rigorous of such uniform appearance or stability as to meet the requirements of the public when asking for "yellow basilicon," or the more exacting variety of the pharmacist as to what a good ointment is supposed to be. After trying various formulae from continental pharmacopoeias with no better result, we had to fall back upon certain modifications of our own B.P. Feeling strongly that, generally speaking, the less heat employed in making the matter, we used the equivalent components of the ung. simplex, and remembering that our grand old teacher—Dr. Redwood—used to caution us against the lighter coloured and more opaque pine resin as being a hydrate and not properly soluble in melted fats, we chose which we think should be called "rosin" from its dark, bright amber colour, approaching to a rosy red. To save so much stirring whilst on the water-bath we devised the plan of scattering (not sifting) this in powder over the surface of the liquid mass, which answer better than we had expected, each instalment of added rosin dissolving at once before it could reach and agglomerate at the bottom of the vessel, finishing off an article of first-class character in half the time, and with less than half the exposure to heat formerly required. With very great respect I would suggest that my fellow-worker repeat his experiments for himself, and be sure to keep the product for at least six months, then to take cutlets from the centre and compare with the circumference, then if the results are in every sense satisfactory I shall—if I have the chance—admit most frankly my judgment too hastily formed, and if I have not the chance, I feel sure he will forgive just the same. Yet I cannot close without saying that I think those ideas arise from a mistaken view of the case for the shrinkage of fats when left to cool of themselves. That cause will, I think, be found in the different physical structure of the mass, resulting from an effort of the components to assert each its own individuality as much as possible, a tendency which judicious stirring helps to keep in check. Why, you cannot incorporate water (either liquid or vapour) by simple stirring with melted fat; if you wish to incorporate either water or glycerin there is a point in the cooling process when you may do it by dexterous heating, and then you get in air as well, which results in the formation of a more or less unstable cream—but this is beyond the present question.

West Marylebone.

J. C. Hyssel.

**The specimens sent include the ointments of red oxide of mercury, carbolic acid, boracic acid, and resin. They are all of very satisfactory consistence, and the rosin ointment is particularly fine sample, considering the length of time it has been made. [Ed. Pharm. Journ.]

Answers to Correspondents, etc.

"Student."—The metal is, of course, in an extremely fine state of sub-division, but opinions differ as to the extent to which oxidation may take place under normal conditions. The subject has never been properly investigated.

Diary of the Week.

Tuesday, October 2.

Wednesday, October 3.

Pharmaceutical Society of Great Britain, at 11 a.m. Council Meeting.

School of Pharmacy, School of Pharmacy, at two of at 3 p.m. Distribution of Prizes by the President, Mr. Michael Carteige.

Introductory Session Address by Mr. Walter Hills. Pharmacy Club, at 5.45 p.m.

Dinner at the Café Royal.

Thursday, October 4.

Chemists' Assistants' Association, at 8.30 p.m. Inaugural Address by the President, Mr. R. H. Jones.

Friday, October 5.

Quellet Microscopic Club, at 7 p.m. Exhibition of Objects.

THE PHARMACEUTICAL SOCIETY AND ITS WORK.*

BY WALTER HILLS,
Member of the Council of the Pharmaceutical Society.

One of the three objects for which the Pharmaceutical Society was founded in 1841 was the "advancement of chemistry and pharmacy, and the promotion of an uniform system of education for those who should practise the same."

So impressed were its enlightened founders with the importance of this branch of their work that they took immediate steps to provide a school of pharmacy, not by instantaneous courses of lectures in connection with it were delivered in this house. Such lectures, together with practical laboratory instruction, have been continued to the present time, and we are now met to offer our congratulations and present prizes to the successful students of the fifty-second session, as well as to welcome those of the fifty-third.

This and similar occasions may be regarded as annual field-days of the educational work of the Society, and they afford fitting opportunities for the consideration of all matters relating to pharmaceutical education.

Prior to 1868 it was not the custom to have a formal address at the commencement of a new session, but in that year Mr. H. B. Brady was asked to undertake the duty, and this was the beginning of a series of admirable addresses, about half of which have been delivered by prominent members of our own body, and the remainder by men of science interested in our work, though not belonging to our calling. The Council has conferred upon me a great honour in requesting me to give the address on the present occasion. I assure you, that only after much hesitation have I accepted the important duty, for I feel fully conscious of my inability to speak to you with the eloquence and authority of my distinguished predecessors, all of whom had more claim on your attention than I can expect. Still, loyalty to my colleagues and to the Society bids me undertake the duty, and I must ask you to overlook its shortcomings. It so happens that address of Mr. Brady, which lies between the present occasion and the evening meeting which inaugurated the first session of the Society's school, and this fact suggested the idea that it might be interesting and instructive if I recalled to your minds a few of the incidents of 1842 and 1868, particularly those in any way bearing on that branch of the Society's work which specially claims our attention this evening, namely, pharmaceutical education.

In January, 1842, some seven months after the organisation of the Society, the first evening meeting for scientific discussion was held on these premises. Unfortunately the distinguished President, William Allen, F.R.S., was prevented through indisposition from attending, and his address was read by the Vice-President, Mr. Payne. Papers were also read by Squire and Redwood, and in the discussions which followed appeared the familiar names of A. T. Thomson, Bell, Ince, Wilkinson, and Morson. This was the first of many such gatherings held during that year, and it appears that not only in London, but at Exeter and Bath, as well as at other provincial centres, similar meetings were held.

On May 11 an introductory lecture to a course on general and medical botany was delivered by Dr. A. Todd Thomson, and a few days later the following lecturers were appointed for the winter session:

Dr. A. Todd Thomson . . . Medical Botany
Mr. Geo. Fownes . . . Chemistry
Mr. Redwood . . . Pharmacy

To make the note of these earlier appointments complete I may here mention that Dr. Jonathan Pereira was elected Professor of Materia Medica in 1843, from which date until his death he was inseparably connected with the progress of the Society's educational work, and his memory is perpetuated in the medal which bears his name, and has been presented this afternoon.

On the same day that Fownes and Redwood received their appointments, Thomson commenced his course of lectures on botany, and it is on record that upwards of forty tickets were taken for the course.

In September Mr. Redwood should have given an introductory address preparatory to the winter course of lectures, but he was unable to do so in consequence of a severe cold. And it was on that occasion, to which I have already alluded, that Mr. Payne, the Vice-President, who seems to have been a ready and fluent speaker, gave an admirable address to the students. He was fully conscious of the value attaching to advanced education, and he felt it was of the utmost importance that the pharmaceutical chemist should aspire to a higher intellectual level than that of the ordinary tradesman. Hear what he says, and the words, with one or two minor alterations, might be used to-day:

"In these remarkable times, when education is everywhere spreading, when literacy and mechanics' institutes are flourish ing, when medical and surgical schools are multiplying on every side, shall the chemist and druggist, who is entrusted with so large a share in the preservation of the public health, be behindhand in a strenuous effort to obtain a thorough acquaintance with an art and science which connects him with a noble profession, and demands and is worthy of the full and energetic application of the human mind?"

Finally, the first associate (by examination) was admitted in November, and the second in December of that year. I may also mention, in passing, that the subjects as arranged at that time for the Minor—which was then intended as an assistants' examination only, and gave the associatehip of the Society—were the pharmacopeia of the London College of Physicians, prescriptions, and practical pharmacy. For the Major, the same subjects were taken, but a greater degree of proficiency was required, with the addition of the sciences of chemistry and botany and the rudiments of toxicology.

These few details, taken from the records of 1842, are sufficient to impress us with the foresight and unselfish loyalty to their call.

* Introductory Sessional Address delivered at the commencement of the Fifth Session of the School of Pharmacy, October 8, 1864.

VOL. LIV. (Third Series, Vol. XXV.), No. 1367.
ing of those eminent men who founded this Society. We cannot fail to be struck with their tenaciousness in keeping up a rapidly and thoroughly the work of raising the educational status of those who were to follow them. Their enlightened efforts in this and other directions were speedily recognised, for in the succeeding year, 1843, a Royal Charter of Incorporation was granted to the Society.

For many years after the institution of the School of Pharmacy, practical chemistry was taught in a laboratory in the basement of the Society's premises, but the accommodation being found insufficient, a new one was then established and constructed in 1860. This undertaking was rendered practicable by the receipt of a handsome legacy from Jacob Bell, whose name will always be mentioned here with the profoundest respect and gratitude, for to him, perhaps, more than to any one individual is due the early successful work of the Pharmaceutical Society.

We now pass on to 1868, a year, for many reasons, the most important in our annals, because Parliament then recognised that it was necessary for the safety of the public that those who called themselves chemists and druggists, and who handled poisons, should prove their qualification for the title they claimed, and for the important operations they were called upon daily to perform.

I need not here discuss political matters, but this I may say, that if all who at that time practised pharmacy had been earnest and united in their efforts and demands, a more satisfactory Act than that of 1868 would probably have been passed. However, there is very much that is good in the Act, and certainly its chief feature, which insists on the possession of competent practical knowledge by chemists and druggists, commands itself to all who desire the advancement of pharmacy. Though the Pharmaceutical Society did not in this Act obtain all that it asked for, its good work in the past and its useful organisation were fully recognised, for to it was entrusted the compilation and maintenance of the official register, as well as the duty of conducting the necessary examinations. It is difficult to imagine what might have happened if public opinion had compelled the legislator to pass a Pharmacy Act, and Parliament had not found an organisation already in existence capable of carrying on the duties necessary to the working of such an Act. It is quite true, and perhaps a little humiliating, to call to mind that most of the continental nations had already laws insisting upon the training and qualification of pharmacists, but their examinations were and are still conducted, and their businesses carried on, under very different conditions from those which we, in our greater love for independence and freedom from direct state control, would be likely to imitate.

As I have before mentioned, the inaugural address to the students in 1868 was delivered by Mr. H. B. Brady, whose name and memory will ever be honoured amongst pharmacists, and whose life was all too short for the cause of science. Words spoken by a man of his eminence must ever remain of value to students of every time, and his thoughtful and eloquent address well deserves to be read by all.

The consideration of the then recent enactment of the Pharmacy Act led him to make some very valuable remarks on the aspect of pharmacy in its own and social relations. He points out how with new powers arose increased responsibilities, and he earnestly counselled his hearers to prove themselves worthy of their improved position.

He also mentioned in satisfaction the sympathy of the medical profession generally with the objects of the Act, and this led him to speak on practices which I fear still have a tendency to prevent the complete harmony between that profession and our own, for which we all so much desire—I refer to "prescribing by chemists and dispensing by doctors" and that should just lie to the turn of these points, because I am persuaded they are still subjects of the utmost importance, though I am aware that they require to be treated with the greatest delicacy.

With the largely extended equipment of knowledge now demanded of both the medical man and the pharmacist, it might be hoped that there would be a growing tendency for each to restrict his professional work to that portion of it for which he had been specially trained. Whether prescribing by chemists or dispensing by doctors, it seems to me that it is a necessity that we both should know and it is difficult to obtain definite information on the point, but sure I am of two things:—1st. That this Society will continue to set its face against all intrusions on forms of practice which properly belong to the medical profession, and 2nd, that the more highly trained the pharmacist is for his calling, the less likely he is to overstep the bounds of his legitimate work. Whilst ever willing to make use of his knowledge for the relief of suffering, he will be anxious not to place himself in a false position and assume a responsibility for which his training and education have not qualified him. He will, moreover, set his face against all forms of quackery. Then, as to dispensing by medical men, I fear that this custom is still almost as prevalent as it was in 1868, and though it is in some cases necessary, its discontinuance, where practicable, would be of immense advantage to pharmacists who are complaining of the almost complete want of the work for which they have been specially trained, and would also tend to prevent a good feeling between the medical man and the chemist which we all desire so earnestly.

The valuable advice to the students in Mr. Brady's address was focussed in the word "thorough," which, as has been well said, was the watchword that had long guided his own efforts.

I cannot pass from 1868 without saying a few words about another of our distinguished pharmacists—Mr. Daniel Hanbury—who in this year was President of the British Pharmaceutical Conference which held its meeting at Norwich. In character, surroundings, occupations, and length of life there was a remarkably close resemblance between Brady and Hanbury. Both were connected with the Society of Friends; both were personally engaged for many years in the conduct of historic pharmacies from which they subsequently retired; both held office and did most loyal work for the Pharmaceutical Society; both carried out original investigations of such merit that they were elected Fellows of the Royal Society; and both, alas! died comparatively early, in the prime of their scientific
careers. Moreover, there was in the characters of both a sinuosity and a modesty which is delightful to contemplate. Their work and their careers reflect great honour upon the Society of which they were members, and they have bequeathed valuable examples which all may do well to follow.

Still another name stands prominently forth in this eventful year, and I need hardly say that I allude to that of G. W. Sandford, to whose sound judgment and intense loyalty to the best interests of the Society we owe in a great measure the Pharmacy Act of 1868.

Passing on now to the present year, I call your attention first of all to the prospectus of the fifty-third session of the School of Pharmacy. In the introduction we are told that the School has been developed by the Council of the Pharmaceutical Society into an institution affording a complete scientific curriculum for the pharmaceutical student. And the subsequent pages surely furnish the grounds for this statement. As professors and lecturers we have men of the highest eminence in their respective subjects, whose names it is not necessary to mention, for they are well known to all who take interest in pharmaceutical education. On looking further into the prospectus we find that chemistry, theoretical and practical, botany, materia medica, and histology, as well as the theory and practice of pharmacy, are taught with such completeness that the question may not unreasonably be asked, are those persons—men or women—who make time in a six or ten months' course to take full advantage of all the instruction offered to him?

I think that the answer largely depends on circumstances. If the student possesses good natural abilities, if he has received a liberal general education, if he has been apprenticed to a pharmacist both able and willing to give him a sound practical knowledge of the technical portion of his business, and if, in addition, he has occupied some of his leisure hours in the study of chemistry and botany, or attended courses of lectures on these subjects, then with diligence and persistence, and so long as this school he will not only pass his examinations at the period of the session indicated in the prospectus, but he will be furnished with a fund of knowledge which will be of the highest service to him in the future. The student who does not possess all the advantages I have mentioned will not profit to the same extent by the liberality of the mental fare offered to him, and though he may pass the necessary examinations with more or less credit to himself in the time indicated, I feel convinced that a longer period than the ten months' time which the School of Pharmacy would be of the utmost value to him.

I hope to see the time when, as obtains in most of the continental nations, a compulsory curriculum will be required of all those who present themselves for our examinations. The Council of the Society has during the last eleven years given earnest consideration to this subject. The curriculum clause—or the clause giving power to divide the qualifying examination into parts, and provide for courses of study by those parts—was introduced into the Bill drafted by the Council in 1883, but this draft was not introduced into Parliament. The clause was retained in the 1887 Bill, which was introduced into the House of Commons, but failed to reach a second reading. The Bill introduced into the House of Lords by the late Earl of Milltown, in 1888, also included the curriculum clause. After amendment in Committee it reached the Commons, but was eventually dropped, owing to opposition and the state of public business. In March, 1889, the Bill, generally referred to as the Curriculum Bill, was re-introduced into the House of Commons, but the second reading was never reached. The Council re-drafted a Bill in 1890 containing the curriculum clause, but it was not until March, 1891, that Sir H. E. Rostow introduced it to Parliament, where, owing to the lack of support of the majority of registered men and the active opposition of others, it met the fate of its predecessors. This condensed record clearly shows that the Council of the last few years has been earnest in the matter.

Evidence of previous systematic training on the part of the examiners would be of great service to the students, who would be brought to themselves a compulsory curriculum would be of the greatest advantage. Examinations such as ours are not altogether satisfactory methods of testing the knowledge and capability of candidates, but at present no better plan which can be practically adopted is known. The chief aim of every student should be the acquirement and steady assimilation of scientific principles and methods, and not merely the accumulation of facts, learnt with the primary object of answering the questions of the examination. A curriculum would compel him to devote a longer time to the period of systematic study, and the knowledge thus gained would be more likely to remain with him, and be serviceable to him in after life.

At a recent meeting of the Congress on University Extension, Lord Salisbury, in the course of an excellent address from the chair, speaking on this subject, said "There are great drawbacks to the excessive use of examination. If the object to be gained is a very considerable one, and is much sought after, examination means merciless cramming. It reaches an attempted drive to two or three years the knowledge that should have taken a much longer time. Now that is an old mistake, an old confusion, which we come across so often between mechanical and organic growth. Of course it is comparatively easy to accumulate knowledge in the mind by working ten hours a day and not sparing your health and constitution, if you have them to dispose of; but that is not a healthy growth of knowledge. If you attempted to nourish your bodies in the way in which many people nourish their minds, you would be brought up very quickly. Nature will not stand the food of three years being given in three months." Then, again, a curriculum would of necessity involve the association of students for extended periods of time. This would have two subsidiary advantages—the promotion of professional feeling and of respect for their common calling, and also the intercommunion of ideas on the subjects of study common to all. Private study is useful and necessary, but study in association with others is still more beneficial.

In a short life of Nathaniel Hawthorne, Mr. Henry James, jun., speaking of this distinguished man's earlier years, which were spent somewhat in isolation from the stimulating influence of
of kindred tastes, says:—"The best things come,
as a general thing, from the talents that are
members of a group; every man works better
when he has companions working in the same
line, and yielding the stimulus of suggestion,
comparison, emulation. Great things have been
done by solitary workers, but they have usually
been done with double the pains they would
have cost if they had been produced in more genial
circumstances. The solitary worker loses the
profit of example and discussion; he is apt to make
awkward experiments; he is in the nature of the
case more of an empiric." These remarks
were made with reference to the career of a literary
man, but I think they apply with equal force to
students in other professions.

But, although we have as yet no compulsory
curriculum, our research laboratory offers to the
advanced student the opportunity of continuing his
studies, and of carrying out under very favourable
conditions original investigations.

The institution in recent years of the research
laboratory is yet another proof of the desire of the
Pharmaceutical Society to be in the van of educa-
tional progress, and it is gratifying to find that the
wise and liberal policy which advocated its founda-
tion, and which has fostered its growth, has been
sympathetically recognised not only by individual
leaders in the scientific world, but also by the Royal
Society and other learned societies. As the latest
proof of the value attached to the investigations
conducted in this laboratory may be mentioned the
founding during the present year of a Research
Fellowship of £100 a year by the Salfers' Com-
pany.

We have now rapidly reviewed some of the lead-
ing incidents directly or indirectly connected with
the educational work of the Society during the last
fifty-two years, especially at the three periods men-
tioned, and we may confidently say that the Phar-
maceutical Society has nobly and liberally carried
out its purpose of "advancing chemistry and phar-
macy."

We have also noted with satisfaction that the
Society's efforts have been cordially recognised by
those who are best able to note the rate of the
advancement of educational progress. The granting of the Royal
Charter of Incorporation soon followed the founda-
tion of the Society's School, succeeded in turn by
Acts of Parliament in 1852 and 1868, whilst at the
present time we have evidence of the goodwill of
such important and representative bodies as the Royal Society, the General Medical Council, and
the Salfers' Company.

No one, moreover, would venture to assert that
this work has not in the main been highly benefi-
cial, but there are, I believe, some who maintain
that the Society has taken an unnecessarily high
standard for its educational work and for its ex-
aminations, bearing in mind the too frequent
character of the business in which a large propor-
tion of our qualified men are subsequently en-
gaged.

There can be no doubt that pharmacists are
passing through very trying times, but I suppose
that each generation is apt to magnify its own
special difficulties. We look back, perhaps, with
some regret and days of more general prosperity,
when there were no limited liability companies and
cutting stores dabbling in pharmaceutical opera-
tions, when proprietary medicines and nostrums
were less frequently prescribed by the medical
profession, when at least the beauty of our fields
was not disfigured by the enterprising advertiser
of quackeries, and when there was less of the
so-called elegant pharmacy, which, though fre-
quently a distinct advance, too often necessitates
the purchase of factory-made products, whilst
official preparations lie undisturbed on the pharma-
cist's shelf.

But, in addition to these changes, many of them
inimical to chemists' interests, there are others
which cannot fail to be regarded as highly beneficial
to the community, and of which the skilled phar-
macist should be prepared to take full advantage.

For example, medical science has undoubtedly
made immense advance during the years which
we have been considering, and in no direction has
this advance been more manifest than in the improved
and ever increasing acquaintance with the causes of
disease. Arising from this increased knowledge,
more careful consideration is given in every direction
to all sanitary and other means that may be adopted
as preventives of disease, resulting in great benefit
to the general health. The pharmacist, bearing
this in mind, should aim to keep himself abreast of
all matters directly or indirectly connected with
sanitary science, and so be in a position not only to
aid the physician in the combat with disease, but
also to render valuable service to his fellow-
creatures, and at the same time improve his own
position both financially and socially.

In this, or in some other equally useful direction,
the pharmacist of the future will probably have to
turn his attention, particularly if the work for
which he has been specially trained, and in which
his very title stumps him as an expert, is not more
liberally entrusted to him. I think it probable
that before very long the medical profession and
the public will learn to recognise more clearly the
essential difference between high class pharmacies
conducted by qualified men almost exclusively
occupied in pharmaceutical operations, and stores
established for the supply, on purely trade lines,
not only of medicines and drugs, but also of every
required sort of daily life.

But what can be done to hasten this improved
condition which we all so much desire? The only
two means that I can suggest are individual excel-
lence and corporate loyalty. I think I have shown
that, as a corporate body, the Society has from
its foundation continuously encouraged advanced
education, and that recognition of its efforts has
invariably followed. May we not, therefore, hope
that, as in course of time considerable scientific
acquirements are the possession not only of the
few, but also of the great mass of pharmacists, a
more generous recognition will be granted by the
public?

Then as to corporate loyalty—involving some form
of combination and co-operation for mutual defence
and the advancement of interests common to all its
members. The Pharmaceutical Society was founded
not only for the advancement of education, but also
for the "protection of those who carry on business as
chemists and druggists." Is it not strange then that
such a large proportion of registered men hold aloof
from combination with their fellows, and is it not
all the more strange that many who have been educated in
its school and have, as it were, eaten of its bread,
should turn their backs on it when once their examinations are passed.

I trust that all the students whom I am addressing will become loyal and energetic members of this Society, and that many will be able to render it important services. Do not listen to those who raise the cry "job," and say that the Society does nothing for trade interests. The Society has done excellent work in the past, and that in spite of the lukewarmness of some of its members and the hostility of many who remain unconnected with it. But if different results would have followed if all had loyal co-operation for the common good. And recollect that the policy of the Council is the expression of the views of the members. The success of that policy largely depends on the measure of active support received from all those whose interests are involved.

And now I have left myself very little time to offer you any suggestions as to the way you may best utilise your opportunities whilst working here. I regret this the less because I am conscious that I am not specially qualified to give you advice on this point. But I may, perhaps, if all can gratulate you that circumstances have permitted you to become students in this excellent school. The object of its professors is not only to convey to you in the most interesting and instructive way the knowledge of the sciences on which the practice of pharmacy in its widest sense depends, but also to train you in the best methods by which you may continue the pursuit of science in after life. There is an old saying that "there is no royal road to learning," and if the learning is worth the name, the saying is still true. We are living in days when science is making immense strides in every direction, and it is all the more necessary, as time is still limited, for the student to concentrate some of his attention on those departments which offer to him the greatest attractions, or to those which will be the most serviceable to him in the future.

These are days also when the pursuit of science is made very attractive, when more than ever "of making many books there is no end," and when every facility is given for the acquisition of superficial knowledge. Herein there is no little danger, and it is of great importance that the student should cultivate the habit of thinking for himself, and conquering difficulties as they arise without a too hasty and too frequent resort to his text-books. The acquisition of this habit will enable him more readily to make practical application of his knowledge, and so be in a better position to solve the problems and overcome the difficulties of after life. Generally, the most successful men are not those whose memories are stored with the greatest number of facts, but those who are able to utilise and apply the knowledge they have patiently acquired in earlier days.

It is needless for me to add that diligence and perseverance are as much needed as ever to ensure success, either in this school, at the examination table, or in business life.

You will necessarily utilise most of your time outside the laboratory and lecture theatre in private study, but you will do wisely to take personal interest in the meetings of the School of Pharmacy Students' Association, where you may acquire the habit of expressing your ideas with ease and accuracy.

Your physical as well as your mental powers will require exercise. May I suggest that those of you who are able should become active members of the school football and cricket clubs? The association for recreative purposes of those who have many interests in common is very beneficial, and often leads to lifelong friendships.

Finally, in the name of the Council I congratulate not only those who have taken prizes this afternoon, but also those who, though unsuccessful in this respect, have done good and honest work. I trust that all the students of the last and present sessions have before them a future in which both they themselves and the Pharmaceutical Society will have cause to rejoice.

POISONOUS PLANTS OF SOUTH AFRICA.

J. Medley Wood, the Curator of the Durban Botanic Gardens, has recently issued notes on local poisonous plants with the view of making them better known, and so preventing accidental poisoning by them. The following are some of the plants mentioned:

*Lasianthus antikholoides*, Melan.—The roots are very acid, like Mesereon and other plants of the same order (*Thymelacca*) to which it belongs. It has bright yellow flowers, in terminal clusters, very conspicuous, and sweetly scented in the evening. Unlike the Mesereon it has ten stamens, and there are five scales alternate with the lobes of the perianth. The roots are said to be used by the natives as an antidote for snake bites, but great caution is observed as to the quantity administered.

*Lechadostenia interrupta*, E. M.—An umbelliferous plant, the root of which is used by the natives as a remedy for colds. Dr. A. Smith (of Lovedale) says it certainly has the power of giving an immediate headache.

*Cobretum bracteatum*.—The fruit of this plant is locally known as the "hicoop" nut, and by the natives as "Umantawha." The plant is a climbing shrub with ovate leaves and terminal spikes of dull red flowers. The fruit is an oblong nut with a pleasant flavour, but causes violent hiccough if only a few are eaten. At one time Mr. Wood tried them on himself, and did not care to repeat the experiment. An allied species, *C. erythrophyllum*, Sand., is known as "Umduka," distinguished by its papery four-winged fruits, and its leaves turning almost white before flowering, but reddish in the autumn, is stated by Mr. J. Kirkman to be used as a medicine by the natives in the dose of 3 oz. or less, but an overdose causes death.

*Tepprosia macropoda*, E. M.—This leguminous plant, known to the natives as "Ityoxaan," is not uncommon in the colony of Natal. The roots are used for stinging fish, and for freeing dogs from vermin.

*Physotocoma stricta*, Hoffm.—In the Cape Colony this is known as the "wild sweet potato." Dr. A. Smith says that three brothers had been eating a portion of the tubers when out in the field, and were poisoned. They were recovered by giving them an emetic, though one of them was in a state of collapse. An allied species, *P. abyssinica*, is used medicinally by the natives.

*Aconochroa venenata*, Don.—All parts of the plant
are more or less deleterious. It is known to have formed the chief ingredient used by the Bushmen for their arrow poisons. A Bushman in the employ of Colonel Bowker stated that it is prepared as follows:—The bark is pounded between stones, boiled for some time with water, then strained and the water again boiled until a jelly is formed, into which the point of the arrow is dipped. Dr. Andrew Smith says that a little fresh juice of Ephedra is added after boiling, and that no snake poison or other substance is used. He also says that in the Transvaal the poison is extracted from the fruits, and that it is more abundant in the seed. The plant has also been used by the natives for snake bites and medicinally in other ways, and Dr. A. Smith cites two fatal cases which followed its use. Mr. Wood believes that A. fastigiatia, which has larger, white, fragrant flowers, and much larger, oval, black fruits, about the size of a cherry, is also poisonous.

Buphane disticha, or B. toxicaria.—This bulbous plant, known to the natives as “Inowadi,” has the reputation of being poisonous, and is reputed to have been one of the ingredients used by the Bushmen to poison their arrows. It has also been used as a remedy for “redwater” in cattle.

Hemanthus natalensis.—Another bulbous plant, the fruit of which forms a globose red berry, is also reputed to be poisonous. Hemlock, stramonium, and the physic nut (Jatropha curcas and J. multifida) are also enumerated amongst the poisonous plants of the colony.

TRADE OF BAGHDAD AND BUSHIRAN.

Galls.

A large stock came to market during 1883, principally carried forward from 1882, and over 10,000 bags were shipped to London and Continental markets, principally to the former. Average price in the beginning of the year was about £12 6s. 7d. per cantar of 223 caks (about 490 lbs.). The new season’s crop which began to come forward in October, was also sold at such price to commence with, but fell to £11 16s. 9d. before the close of the year, and greater part of the crop was still on hand at the end of the year, owing probably to depression existing in French silks, for the drying of which this nut is largely used.

GUM TRAGACANTH.

The imports were very large, and between 6000 to 7000 cases were shipped during the year, principally to London, but owing to the absence of demand in the home markets not much business was done until the year was well advanced, and at the end of it some 400 or 500 cases remained unsold. This article comes from Kermanshah, Barna, Kurdistan, and Bulimania.

LIQUORIC ROOT.

There are many enquiries for the low quality available in this country, but the trade might be made a valuable one were greater care bestowed on the drying and preparation of the root for shipment. It grows wild in many parts of the country on the banks of both the Tigris and Euphrates, and can be obtained at cost of the labour required to collect it.—Consular Report.
for being proud of the Fund as a means of relieving the necessities of their less fortunate brethren. If the Committee were in a position to grant more annuities the capability could be advantageously exercised, and in reference to this point Mr. Causs stated that he had been struck by the very generally entertained opinion that cases of distress should be relieved in that manner by the Pharmaceutical Society. He hoped, therefore, that increased subscriptions would come in during the next twelve months, by which the Committee would be enabled to provide for further annuities, without interfering with its power to render assistance by grants for special emergencies.

Some discussion took place in consequence of a remark by Mr. Hampson in reference to the present method of election, which he regards as objectionable. Without desiring to re-open that question he suggested that members of Council should individually abstain from exerting their influence in favour of any particular candidate for an annuity. Mr. Rymer Young stated that he was in full sympathy with Mr. Hampson in regard to this matter, and thought that the Council would have no difficulty in selecting the cases having the strongest claim upon the Fund so as to relieve the candidates from the expense of canvassing now requisite, and some of them from the disappointment arising from failure. Mr. Harrison also gave expression to his sympathy with the sentiment of these remarks, but characterised the suggestion made by Mr. Hampson as illogical. Though agreeing with him that the selection of annuitants should be left entirely in the hands of the Council he was not disposed, as a member of Council, and therefore one of those who best knew the circumstances of the different cases, to abstain from giving effect to the influence he could thus exercise in promoting the success of particular candidates. For the same reason he would be indisposed to refuse advice to voters who very frequently applied to him for information as to the most deserving cases. It appears, indeed, as remarked by Mr. Hills, that Mr. Hampson's suggestion, if fully carried out, would actually have the effect of preventing individual members of Council from using their votes in an election. In fact, the objection to the method by which annuities are obtained—though estimable for its motive—is founded too much upon regard for abstract principles of justice to be applicable to existing conditions. It is more in consonance with a state of affairs in which the equally objectionable injustice of poverty or distress would be itself non-existent. The impossibility of granting annuities to three out of the seven candidates who have been selected is in itself an injustice to them, but being unavoidable it is no more an injustice than the necessity which
makes all the seven candidates anxious to be elected. Would not some, if not all of them, think it a still greater injustice to be denied a chance of election, and debarred from seeking the assistance of friends in furtherance of the object they have in view? As Mr. Atkins pointed out, the necessary failure of some of the candidates and the exclusion of others from the recommended list are matters apart from the motion that was before the Council, and like the struggle between candidates, they must be accepted as inevitable concomitants of the evil which the Benevolent Fund is intended to mitigate.

In addition, it must be remembered that the desire of many subscribers to the Fund to make it of service in the relief of cases they are specially acquainted with and take interest in is a circumstance of great importance. There is great reason for the opinion expressed by Mr. Atkins, that if the power of voting were done away with many subscribers would lose interest in the Fund, and in time cease to contribute to it.

In connection with the receipt of an official report by Mr. Henry Craig on the subject of the leaving certificates given by schools in Scotland, the President drew attention to the circumstance that these certificates are now being accepted by many authorities in the place of the preliminary examinations previously held by them. He hoped that in time these certificates would be taken advantage of by pharmaceutical candidates.

In mentioning the resignation of Mr. Lawrence Russell as Local Secretary at Windsor, the President requested the Council to authorise his writing to express regret at his retirement and thanks for his long services to the Society.

In reference to a letter from Mr. Braxton Hicks, the coroner for the South-Western district of London, enclosing a recommendation for regulation of the sale of carbolic acid, it was decided that Mr. Braxton Hicks should be referred to the Privy Council.

The report of the General Purposes Committee gave a statement of the progress made with cases relating to the administration of the Pharmacy Acts. A large number of penalties have either been paid or recovered under judgment. Several cases are still to be tried, and proceedings were ordered to be taken in other cases.

**ANTIDIPHTHERIC SERUM.**

One of the subjects exciting the greatest interest at the meeting of Naturalists and Physicians at Vienna last week was the treatment of diphtheria by means of a prepared serum. In a paper read by Dr. Behring, the opinion was expressed that the preparation of serum for the purpose should be undertaken by the State, under the direction and control of the sanitary authorities. It was stated that among children the mortality from diphtheria, amounting now to 240 in 10,000, might thus be reduced to one-third of that rate.

Dr. Ehrlich spoke of this method of treatment as one of the most important results known in the history of medicine, and he stated that trials made in the Berlin children's hospitals showed that without the use of serum there were twenty-five deaths out of seventy-two cases, while there were only two deaths out of seventy-eight cases treated with serum during the first two days of illness. Anti-diphtheritic serum is therefore likely to become an article in demand for medical use, and pharmacists will require to provide for the supply of it.

**THE OPENING OF THE SCHOOL OF PHARMACY.**

In the inauguration of the fifty-third Session of the School on Wednesday last, a revision was made to the former practice of entrusting the delivery of the Address to Students to a prominent member of the pharmaceutical body, and it was a fortunate circumstance that on this occasion the delivery of the address should have been undertaken by Mr. Walter Hills. His position as the representative of an historic house which was so intimately connected with the origin and establishment of the Society, and has always continued to be the source of important influences in promoting the objects with which it was founded, gave additional interest to his retrospective view of the past work of the Society as an educational body and as an organisation for pharmaceutical advancement.

From both points of view Mr. Hills' address may be read with profit by both old and young connected with the business of pharmacy, and we commend it to their careful consideration. The remarks of Sir Richard Quain in proposing a vote of thanks to Mr. Hills for his address, and those of Sir Alfred Garrod in seconding the motion were of a nature not only calculated to be gratifying to him, but serviceable in showing the high estimation in which the Society's work is held by leaders in the medical profession, and the just appreciation entertained by them of the proper relations between medicine and pharmacy.

**MEDICINE STAMP DUTY.**

From the thirty-seventh report of the Commissioners of Inland Revenue, which has just been issued, it appears that there has again been a decrease in the amount of revenue from medicine stamps to the extent of £7,115 as compared with the receipts in the previous year, when the decrease in the revenue from that source amounted to £19,737. The duty paid for medicine stamps still amounts to the large sum of £213,210, and the number of licensed vendors in the United Kingdom to 29,304.

**DEATH OF AN ANNUNTEA.**

We regret to have to announce the death, at the age of 74, of Mrs. Anne Hury Rosseter, widow of the late John Rosseter, chemist, formerly of Notting Hill, and daughter of the late Joseph Gifford, President of the Society (1852-1853). Mrs. Rosseter was elected an annuant on the Benevolent Fund in 1886.
Transactions of the Pharmaceutical Society of Great Britain.

MEETING OF THE COUNCIL.

Wednesday, October 3, 1894.

Present—

MR. MICHAEL CARRIGHIGH, PRESIDENT.

MR. WILLIAM GOWEN CROSS, VICE-PRESIDENT.

Messrs. Abraham, Allen, Atkins, Bottle, Goettleig, Greenish, Hampson, Harrison, Hills, Johnston, Martin, Newholme, Schacht, Southall, Storrar, and Young.

The minutes of the last meeting were read and confirmed.

ELECTION OF ASSOCIATES.

The following, having passed the Minor examination, and tendered (or paid as Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Couper, Frederick Thomas ... Edinburgt.

Openshaw, John Wm. W. ...... Lower Darwen.

Robinson, Edward George ...... Lincoln.

Sutherland, John George .......... Sunderland.

ELECTION OF STUDENTS.

The following, having passed the First examination, and tendered their subscriptions for the current year, were elected "Students" of the Society:—

Allison, Joseph Wm. W. .......... Cockermouth.

Bannister, Frank Ewart .......... Netherton.

Buchanan, Alexander G., Jun. ... Govan.

Charlesworth, Charles E. ...... Manchester.

Cox, George Packer ............. Guernsey.

Cruce, Harry Douglas .......... London.

Duncan, Robert .................. Fortrie.

Gayton, Ethel ............... Hampstead.

Harvey, John .................. Constantine.

Hogarth, John Tom ........... Chipping.pton.

Jones, Edward Rogers .......... Oswestry, reeeption.

Lee, Harry L. .................. Bridlington Quay.

Mason, Ernest Noel ............. Bexley Heath.

Richardson, Joseph Marius ...... London.

Stratton, William George ...... Uckfield.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a nominal restoration fee of one shilling.

RESTORATION TO THE REGISTER.

The name of the following person was restored to the Register of Chemists and Druggists:—

William Jones Williams, 13, Arthur Road, Holloway, London, N.

THE INTERNATIONAL CONGRESS OF HYGIENE AT BUDAPEST.

The PRESIDENT read the report which had been written by Dr. B. H. Paul, who was appointed delegate to represent the Pharmaceutical Society of Great Britain at this Congress. He stated that he had received a most friendly and hospitable reception, both from the officials of the Congress and individual members. Much satisfaction was expressed that the British Society had sent a representative, and at the proceedings of the pharmacy section, which was constituted for the first time, he was appointed honorary president of the section. He also took the opportunity of reporting that he had attended the meeting of the German Apotheker Verein at Cassel, where he also received a hearty welcome.

The PRESIDENT added that he was sure the Council would feel great satisfaction in hearing that their representative had been so well received, both in Germany and at Budapest.

REPORT OF FINANCE COMMITTEE.

The report of this Committee was of the usual character, and recommended the payment of sundry accounts.

The PRESIDENT (as Chairman of the Committee), in moving the adoption of the report and recommendations, said it contained nothing special to which attention need be called. The receipts and payments were of the usual character. With respect to the Benevolent Fund, they did not at this time of the year expect to receive many ordinary subscriptions, but a sum of £11 had come, as well as a donation of ten guineas.

The report was then put and adopted.

REPORT OF BENEOLOVENT FUND COMMITTEE.

The report of this Committee included the recommendation of the following grants:—

£13 to be placed in the hands of the local secretary for a registered chemist and druggist (66) who has had two previous grants of £13 each. (Landport). £13 to the widow (60) of a member and subscriber to the Fund. (Motherwell, N.B.). £5 to an associate (52), who had a similar grant in January, 1893. (Wrexham). £6 to a registered chemist and druggist (68), and subscriber to the Fund. He has had two previous grants of £6 each. (Liverpool).

One case the Committee had declined to entertain. The Secretary submitted a statement with regard to the annuitants, showing that in October, 1893, there were forty-four on the list, and four were added in December.

One annuitant had died during the year, and two had resigned, leaving on the list forty-five. The Committee had recommended that four more annuitants be elected on Tuesday, December 11.

Having considered the cases of applicants whose names had been placed upon the provisional list of approved candidates for an annuity since the last election, as well as those of other applicants during the year, the Committee had recommended that the following, who had been deemed to be the most necessitous, be placed on the list of approved candidates for election in December next:—

Board, Thos. F. (66), Cheltenham.
Troughton, Christopher (78), Liverpool.
Willison, Elizabeth A. (88), Bath.

The following were the unsuccessful candidates at the last election:—

Bromfield, Chas. (76), Exeter.
Ellis, Elizabeth (80), Burnham (Essex).
Kershaw, Ellen (64), Wheathamstead.
Watson, Jas. B. (86), Chippenham (Lancs.).

The VICE-PRESIDENT (as Chairman of the Committee), in proposing the adoption of the report, drew the attention of his colleagues, and through them that of chemists throughout the country, to the case of Miss A. Wells, aged 58, who was seeking an annuity at the hands of the United Kingdom Benevolent Association. She is the only daughter of Mr. W. Wells, who for upwards of fifty years was a well-known and respected inhabitant of South Acton, where he carried on a chemist's business. He was a well educated man, having been brought up at Eton, and was universally respected; but he was unfortunate in business, and at his death left a family almost wholly unprovided for. Miss Wells, since his death, had worked in a hard and most praiseworthy manner, but with advancing years and in failing health had
been compelled to apply for assistance. Her case was recommended by, amongst others, the Lord Bishop of Quebec, the Rev. J. McArthur, Dr. Vine, Henrietta Street, Covent Garden, and others, and as he found on looking through the list of subscribers to the Benevolent Association the names of several residents in his own town whom he should solicit for their support. While he was not disposed to say that he might have a similar experience, and with their united aid he trusted Miss Wells would be successful in her application.

The President said it might be as well to explain that Miss Wells was ineligible for assistance from their own fund, as it was not intended for "orphans." The resolution was then put and carried.

The Vice-President then moved that four additional annuitants be elected on the Benevolent Fund, and that the election take place on December 11. He wished the Committee could have recommended that a larger number be elected. It was not for want of eligible candidates that the number was restricted, but simply from lack of funds. It was wonderful how ready everybody was when they knew of a case of distress to recommend that the Pharmaceutical Society should apply to for an annuity, and it could not be disputed that many more annuities ought to be granted than were granted in the main. Many members were proud of the Fund, and were pleased that the faith placed in the members as a whole had been so far justified. The income from their invested capital would nothing like provide the amount required, but subscriptions had come in, and he hoped would come in during the next twelve months on an increasing scale, so that the annuities might be provided for without diminishing the casual grants.

Mr. Schacht seconded the motion.

Mr. Hampson said he should have liked to elect the entire number of eligible candidates, and to have done so without the process of voting, and though this was impossible, at any rate he thought the four might have been elected in a manner which would be above all suspicion, viz., by the Council itself; but inasmuch as the abuse, as he considered it, still remained, he supposed the usual method must be adopted. He would not attempt to reopen this question now, but he would say that, in his opinion, the Council should not allow their names to be used on the cards and circulars of individual candidates. Some years ago he made a similar suggestion, and some members then agreed that it was not a wise thing to do, and that members of the Council should not throw their weight in any particular direction. While these miserable struggles went on he thought they ought to let the unfortunate candidates and voters fight it out amongst themselves.

Mr. Young said the method of selecting annuitants had been so recently before the Council that it was perhaps hardly right to raise the question again; at the same time he must express his sympathy with the tone of Mr. Hampson's remarks. It seemed to him that the Committee, which last night had no difficulty in weeding out four or five cases which were weaker than the others, would have had no difficulty either in selecting the four which were the strongest. These seven selected candidates would be quite a considerable amount of expense, and some of them to disappointment, and he could see no earthly use in it. As the Vice-President had said, the number to be elected had to be regulated not by their sympathies but by the amount of funds in the Treasurer's hands. He agreed with Mr. Hampson's remarks as to the mode of election, thought he took up a somewhat illogical position in the suggestion he had made. He contended—and there he agreed with him—that the election should be left in the hands of the Council, and yet he objected to those who best knew the circumstances of the different cases giving any assistance to the voters at large. Very often subscribers applied to him for information as to which candidates were most deserving of support, because they themselves had not the means of ascertaining the circumstances fully, and he had always responded readily to such applications, but if he were to do this he knew Mr. Hampson had given, and carry it to its logical conclusion, he must tell his friends to look through the papers and act on their own judgment. He was not disposed to act in that way. Like previous speakers he regretted that the whole of the candidates could not be elected, and it was a pity that the number was not doubled. There were evidently deserving cases that had to be excluded simply from financial considerations. He could not help feeling that, if chemists generally would only ponder on the amount of good which might be done by increasing their subscriptions, they would come forward more liberally, and they would then have to exclude deserving cases from the consideration of the voters. He trusted this matter would be considered by the craft, and that larger funds would soon be placed at their disposal.

Mr. Atkins said the exclusion of two or three cases from the recommended list had not been done to do the candidates justice. They were men against whom the Council was not indifferent. He thought the question of the mode of election had better rest for another year, and did not wish to place himself in any antagonism to the extremely generous view taken by the Treasurer, but he felt sure that whenever they did venture on the experiment which he recommended, he would himself be started at the number of persons who would withdraw their subscriptions when they lost their votes. The Vice-President had that morning invited chemists to assist in any way they could in the election of a lady to an annuity from the Benevolent Society, and this could only be done by canvassing. Some years ago he was interested in a similar case, and the labour which he and his wife had undergone was almost herculean. Surely they were not to withhold their influence entirely from the election. He had never allowed his name to be placed on a card, but it was almost a distinction without a difference to abstain from that and vote on one of the candidates personally or by letter. As long as human nature was what it was, and as long as other institutions were worked as they were, he feared it was utopian to attempt to hold their hands entirely, and thought that it was quite fair for any gentleman to give advice as to the most deserving cases.

Mr. Gorging, whilst for the last twelve months loyal to the suggestions made with regard to candidates, thought the Council should take a neutral position in these matters.

Mr. Hills agreed with Mr. Harrison, that it was undesirable members of the Council, as subscribers to the Benevolent Association, should have their names recorded on the cards for promoting the selection of any one candidate; but to carry this view to its logical conclusion they ought not to use their votes at all. He thought, therefore, that individual members of the Council might legitimately use their influence in promoting the cause of any candidate they thought preferable.

The report was then put and carried.

Correspondence.

The President announced the receipt from the Government of an official copy of the report for 1894 of Mr. Henry Craik, C.B., on the inspection of higher class schools, and the examination for "leaving certificates" in secondary education in Scotland. The Inspector referred to the fact that a number of authorities had announced their readiness to accept the leaving certificate in lieu of such preliminary examinations.
as are held under their directions, including the War Office and the Civil Service Commissioners, the Universities of Oxford and Cambridge, the joint Board of the Scottish Universities for the preliminary examination, the General Medical Council, the Royal College of Surgeons of Edinburgh, the Society of Solicitors before the Supreme Courts, and other bodies. These certificates he (the President) regarded as extremely valuable, and he hoped the time was not far distant when their own candidates would take advantage of them. Like all Scottish educational work, this report was admirably done, and well deserved their consideration.

REIGNITION OF LOCAL SECRETARIES.

The President also said he was sorry to report that a letter had been received from Mr. T. Blackshaw, of Burslem, resigning the position of local secretary to this Society on the ground of ill-health. The appointment of a successor was being considered.

Mr. C. J. L. Russell, of Windsor, had also resigned a similar position, as he was leaving the neighbourhood. He (the President) had for a great many years entered into the candidate of Mr. Russell, who was formerly one of their students, and whom he had long regarded as a type of gentleman who reflected credit on himself and on the profession to which he belonged, and as a proof that an educated man could and must succeed in life. At the close of that brief and fairly successful career, both to himself and his family, he hoped the Council would allow him in its name to write to Mr. Russell expressing regret at his retirement, and thanks for his services to the Society through many years.

The President likewise read letters from Mr. H. A. D. Jowett thanking the Council for his appointment as Assistant Lecturer in Chemistry in the School, and from Mr. T. Tickle in recognition of the grant of £45 from the Manchester Pharmaceutical Association Scholarship Fund, to enable him to continue his work in the Research Laboratory; he also thanked the President of the Manchester Pharmaceutical Association and the founder of the scholarship, the more because he did not belong to the district for which the scholarship was intended.

POISONING BY CARBONIC ACID.

The President said he had received a letter from Mr. Braxton Hicks, Goronme, with reference to an inquest held at Walsdown on September 24., in which death had taken place from carbonic acid poisoning, encasing a rider to the verdict of the jury, recommending that carbonic acid should be placed under the restrictions applying to poisons included in the second part of the schedule, and that it should only be sold in distinctive bottles. He would write to Mr. Braxton Hicks, pointing out that his proper course was to address the Privy Council.

REPORT OF GENERAL PURPOSES COMMITTEE.

The report of this Committee included the usual letter from the solicitors stating the business made with legal cases placed in their hands. A large number of penalties had been paid by or recovered from various defendants. Several cases are awaiting trial.

A large number of cases of infringement of the Pharmacy Acts were reported to the Committee, and proceedings were recommended.

This report was read and considered in committee as usual.

On resuming, the report and recommendations were adopted, and special resolutions were also passed, authorizing the Registrar to take proceedings against the persons named.

OPENING OF THE SOCIETY'S SCHOOL OF PHARMACY.

The fifty-third session of the School of Pharmacy was inaugurated on Wednesday, October 3, the chair being taken at three o'clock by Mr. Michael Carteige, President of the Pharmaceutical Society.

The Dean of the School, Professor Green, was first called upon to read his report on the work of the past session, as follows:-

Report on the School of the Pharmaceutical Society for the Fifty-second Session, 1893-4, by the Dean of the School, Professor Reynolds Green.

The number of students attending the School of Pharmacy during the session has been eighty-three, about the average number for the past ten years.

In the department of Chemistry, Professor Dunstan reports that there were forty seven students. The work of the class throughout the Session was satisfactory in every respect. At the examination in March the Bronze Medal was taken by Mr. G. H. Taylor, and Certificates of Honour by Mr. A. T. Hill. At the examination held at the close of the session in July, the Silver Medal was awarded to Mr. Henry (Bell Schlar), whilst Certificates of Honour were taken by Mr. A. T. Hill, and by Mr. T. Jackson, and by Mr. A. T. Hill.

The Silver Medalist, Mr. Henry, has since been elected by the Council Redwood Scholar in the Research Laboratory.

In this department: Mr. R. H. A. D. Jowett, B.Sc. Lond., has been appointed by the Council an Assistant Lecturer, to succeed Mr. E. F. Harrison, who resigned at the end of last session. During the present Session the teaching of Physics will be extended especially in the direction of practical demonstrations in the use of physical instruments, new apparatus having been recently provided for this purpose by the Council. Considerable encouragement has been given to chemical investigation in Pharmacology by the liberality of the Salters Company, which has founded, in connexion with the Research Laboratory, a Research Fellowship in Chemistry of the annual value of £100.

Professor Aitfield reports that sixty-three students worked in the Society's laboratories during the session, most of them for three hours daily during an average period of between six and seven months. The records relating to the daily work of each student, and to the result of the Professor's weekly revision classes as well as to the Professor's and demonstrators' system of marking the amount and quality of the work accomplished, indicate an average session. The Council's Bronze Medal and two Certificates of Honour, at the end of the winter course, were taken respectively by Charles John Taylor, Aubrey Thomas Hill, and Charles Edmund Ashby. The Council's Silver Sessional Medal was won by Charles Edmund Ashby, and the three Certificates of Honour by Thomas Anderson Henry, Charles John Taylor, and Arthur Lander.

In the department of Botany thirty-nine students attended. With few exceptions the work was done well throughout, Messrs. Hill, Henry, Ashby, and
Taylor being worthy of special commendation. The bronze medal at the end of the first course and the silver medal at the end of the session were both won by Mr. A. T. Hill, but in both cases he was hard pressed by the other three. The certificates of honour at the end of the first course were awarded to Mr. C. J. Taylor and Mr. C. E. Ashby, and those at the end of the Session to Mr. T. A. Henry, Mr. C. E. Ashby, and Mr. C. J. Taylor.

Professor Greenish reports that thirty-seven students attended the first course of lectures on Materia Medica, and twenty-four the second. During the whole session, and particularly during the second course, the work was well maintained and good progress made. The bronze medal and certificate of honour for the first course have been awarded to Mr. T. A. Henry and Mr. A. T. Hill respectively. Mr. Henry has also carried off the silver medal for the session, certificates of honour being obtained by Mr. Taylor and Mr. Lander.

During the past session, thirty-eight students attended the winter term of the course of the Theory and Practice of Pharmacy, and thirty during the summer. The two Laboratory courses of practical manipulation were followed by thirty-one and thirteen students respectively. The bronze medal was gained by Mr. Aubrey Thomas Hill. The silver medal was gained by Mr. Charles John Taylor.

One change in the regulations made by the Council for the award of the School prizes calls for notice in this report. The clause restricting the competition to those students who had not attended the courses of lectures and laboratory work in a previous year has been withdrawn. It is hoped that this change may encourage many students to attend lectures during their apprenticeship.

The Professors and Lecturers are again gratified to find that the School has more than held its own in the open competition for the medals and prizes offered by the Council of the Pharmaceutical Society.

The Pereira medal was won by Mr. A. T. Hill, and the Society’s silver medal by Mr. C. E. Ashby (Bell Scholar).

While regarding the progress of the students with considerable satisfaction, two events have happened during the year which cast a shade of gloom over our proceedings to-day. One of them touches myself, perhaps, more closely than it does my colleagues, but in it we all recognize and feel a deep sense of loss. Our venerable friend and colleague, Emeritus Professor Bentley, has passed away from our midst, after only a few years rest, following a long period of faithful labour in the interests of the School, and indeed of pharmacy generally. Of the details of his successful career there is no need to speak, his memory lives with affection and respect in all our hearts. No professor of our staff ever gained more thoroughly than he the esteem and confidence of those who studied under him. Mr. R. H. Davies, a former student in the School, and at one time one of the Demonstrators in the Chemical Laboratory, has also passed away. Mr. Davies was a member of the Board of Examiners, and Treasurer of the British Pharmaceutical Conference.

After the reading of the report, the President proceeded to distribute the prizes and certificates to such of the successful candidates as were present, offering in each case a few appropriate words of congratulation.

**LIST OF PRIZEES IN THE SCHOOL OF PHARMACY COMPETITIONS.**

**THOMAS JACKSON.**
Certificate of Honour—Session—Chemistry.

**ARTHUR LANDER.**
Certificate of Honour—Session—Practical Chemistry.

**CHARLES EDMUND ASHBY.**
Certificate of Honour—1st Course—Practical Chemistry.
Certificate of Honour—1st Course—Botany.
Silver Medal—Session—Practical Chemistry.
Certificate of Honour—Session—Chemistry.
Certificate of Honour—Session—Botany.

**THOMAS ANDERSON HENRY.**
Certificate of Honour—1st Course—Chemistry.
Bronze Medal—1st Course—Materia Medica.
Certificate of Honour—Session—Practical Chemistry.
Silver Medal—Session—Chemistry.
Certificate of Honour—Session—Botany.
Certificate of Honour—Session—Materia Medica.

**CHARLES JOHN TAYLOR.**
Bronze Medal—1st Course—Practical Chemistry.

Certificate of Honour—Session—Chemistry.
Silver Medal—Session—Botany.

**MR. HANBURY’S GIFTS OF BOOKS.**
The following prize books were presented with the books mentioned, which are given by Mr. Thomas Hanbury in memory of his brother, the late Daniel Hanbury, F.R.S.

To **CHARLES EDMUND ASHBY, 1st Prizeman in Practical Chemistry**, copies of "Pharmacographia" and "Science Papers."

To **THOMAS ANDERSON HENRY, 1st Prizeman in Chemistry and in Materia Medica**, copies of "Pharmacographia" and "Science Papers."

To **AUBREY THOMAS HILL, 1st Prizeman in Botany**, copies of "Pharmacographia" and "Science Papers."

To **CHARLES JOHN TAYLOR, 1st Prizeman in Pharmacy**, a copy of "Science Papers."

**THE HERBARIUM PRIZE.**

Professor Green then presented his report on the competition for the Herbarium prize. The
new regulations recently introduced had now made themselves felt, and he could trace their influence very clearly in the competition on which he had to report. Only two collections had been sent in, one of which, by Mr. John Wishart, of Inshie, was very meritorious in many respects, but there were one or two shortcomings, and he could only recommend the award of a Bronze Medal, and the other one sent in by Mr. Charles Kent, of Brighton, obtained a Certificate of honour.

**COUNCIL EXAMINATION PRIZES.**

The President, in the name of Messrs. Dott and Jack, presented their report on the competition for these prizes. Fifteen candidates competed, and the papers of those who had gained the prizes were of a very high character, though some others were not quite so good as might have been expected. He then presented the medals and books to the successful competitors as follows —

I. PEREIRA MEDAL (SILVER); and Books of the value of £5, presented by the late Thomas Hyde Hills.
   AUBREY THOMAS HILL.

II. PHARMACEUTICAL SOCIETY'S MEDAL (SILVER); and Books of the value of £3, presented by the late Thomas Hyde Hills.
   CHARLES EDMUND ASHBY.

III. PHARMACEUTICAL SOCIETY'S MEDAL (BRONZE); and Books of the value of £2, presented by the late Thomas Hyde Hills.
   FREDERICO WILLIAM GAMBLER.

**JACOB BELL MEMORIAL SCHOLARSHIP.**

Mr. Gerrard, in presenting the report on this competition, said the number of entries was twenty-two, which was rather below the average for the past few years. The quality of the papers, however, was very high; twelve obtained sufficient marks to entitle them to the Scholarship, and the two who stood highest obtained respectively 368 and 346 marks out of a possible 400. These two gentlemen were —

Mr. Harold Brown, and Mr. John Robert Walker,

and the Scholarships had been awarded to them.

With regard to the Manchester Pharmaceutical Association Scholarship, he regretted to have to report that only one candidate came forward, and the examiners did not consider that the answers he gave to the papers were of sufficient merit to entitle him to the prize. This was much to be regretted, and considering the large district from which competitors might be drawn, he trusted that in future years there would be no lack of capable candidates.

**THE REDWOOD SCHOLARSHIP.**

The President, having explained the manner in which this Scholarship is awarded, viz., by the Council, on the report by the Research Committee assisted by the Director of the Research Laboratory, announced that it had this year been conferred on Mr. Thomas Anderson Henry.

He then called on Mr. Walter Hills to deliver

**THE INAUGURAL SESSIONAL ADDRESS,** which is printed at p. 271.

At the conclusion of the address, —

Sir Richard Quain, President of the Medical Council, and honorary member of the Society, said their President had imposed on him a pleasant duty—that of proposing a cordial vote of thanks to Mr. Hills for his admirable address, an expression in which he felt all present would readily join. His remarks had proved full of historical interest, and full of instruction and suggestion, and he doubted not they would be read and appreciated by many who were not actually present to hear him. Mr. Hills was the representative of a house which had been a great support to the Pharmaceutical Society—the house of John Bell and Co., now approaching its centenary, one member of which, Mr. Jacob Bell, he (Sir Richard Quain) had the pleasure and privilege of calling a friend, and he was also a liberal supporter, if he could not describe him as the originator, of this Society. Reference had also been made by Mr. Hills in a merely passing and too modest a way to another valued friend, Mr. Thos. Hyde Hills, a name which would ever be remembered with the highest respect by the Society, and also in general society, as one of the most generous of men. He had heard that it was said in the presence of Thackeray that Mr. Hills was the prototype of the Cherrybie Brothers, upon which some one remarked that that was impossible, as there were two of them. Oh! yes, was the answer to that remark, it was quite possible, for it would take the two Cherrybies rolled into one to make a Hills. However that might be, Mr. Hills' references to-day took him back in thought to the early days of his own studentship—to Anthony Todd Thomson, his friend and teacher, to Pereira and others, on whose names and memories it was so pleasant to reflect as benefactors not only to this Society but to the world at large. Mr. Hills had referred to prescribing chemists and dispensing doctors. For himself he had no objection to prescribing chemists who gave a simple remedy for a simple application; but he did object to those who visited the sick and were guilty of crimes next to murder by doing that of which they had no real knowledge, and for which they were not qualified. He hoped only that a qualified practitioner had opened a shop and rivalled the chemist in trade was as much to be blamed as the prescribing chemist; but he believed that the good education both classes were now receiving would render such lines of practice more limited than they had been, and it would be for the benefit of everyone that it should be so. Mr. Hills had also alluded to quack medicines and ready-made physic. Why should physicians deal in such articles when they had accomplished and educated chemists ready to give their assistance in preparing all that was necessary? When he heard of this ready-made physic he always thought of ready-made clothes; such things did not fit, and were not generally of very good quality. He trusted that feeling would continue, and that they would continue to support that high education of the pharmacist which was for the benefit of the public. Mr. Hills had told them of means taken by the Society to secure that, and he was sure it would continue to do so. He could not conclude without saying a word on what pharmacists had done for the medical profession. His late friend, Professor Rodwood, gave the Medical Council invaluable assistance in the formation of the phar-
macropia, and his work was now continued by Professor Attfield.

Sir Alfred Baring Garrod, in seconding the motion, said he felt it impossible to be absent that afternoon when he saw that Mr. Hilles was to deliver this address, and he had been amply rewarded for coming. Although he had lately had comparatively little to do with the Pharmaceutical Society, he had a great deal to do with its earliest history, for he remembered in 1842 attending a meeting at Mr. Jacob Bell's, at which William Allen, the Hanbursys, and a great many others were present, and he believed that was one of the earliest meetings of the Society. The Society had done an immense amount of good to this country and to the medical profession. He cordially agreed with what Sir Richard Quain had said with regard to prescribing chemists and dispensing medical men—they were both errors. A medical man should confine himself to prescribing and allow the chemist to dispense. With regard to quack medicines, he might say for himself that, following the principles of the Royal College of Physicians, he never in his life, that he could remember, prescribed a drug which was not contained in the pharmacopoeia, or of which the composition was not thoroughly known. As for prescribing a ready-made pill, it was an absurd thing for a medical man to follow the directions of some one of whom he knew nothing. There were no doubt certain drugs which were made up in large quantities, but that ought not to be the business of a medical man. He had the greatest pleasure in seconding the proposition.

The resolution was then put and carried unanimously.

Mr. Hilles, in responding, said it was very gratifying to him to hear Sir Richard Quain speak as he had done of his early relations with Jacob Bell and with his late uncle, and he thanked him especially for coming there and giving expression to views which he was sure would meet with the approval of a number of pharmacists who were not present on that occasion. Both he and Sir Alfred Garrod occupied a position in the medical world which would cause their words to be received with the highest respect, and he thanked them cordially for their presence.

The visitors then proceeded to inspect the School premises and partake of refreshments.

EXAMINATIONS IN LONDON.
October, 1894.

MAJOR EXAMINATION—PASS LIST.
Candidates examined. 26
failed. 15
passed 11

Burrows, Harry.
Davies, Herbert Paget.
Davies, John.
Ford, James.
Gillett, Francis John.
Grieve, James.
Hughes, Joshua Arthur.
Humphrey, John Thrilbeck.
King, Charles Edward.
Parry, Owen.
Thorpe, Albert.

MAJOR EXAMINATION QUESTIONS.

BOTANY.
September 28.—Hours from 10 a.m. to 1 p.m.
1. Report upon the section submitted to you for microscopical examination.
   N.B.—Not more than 15 minutes can be allowed to each candidate for the use of the microscope.
2. Distinguish between the Natural Orders Rosaceae and Ranunculaceae. Name the more important indigenous genera of the Rosaceae.
3. Describe the occurrence of latex in plants. Name any natural orders in which it is found. Mention any medicinal or economic products derived from it.
4. Describe the method of reproduction in mosses.
5. What do you understand by a spurious fruit? Give examples and describe their formation.
6. State what you know respecting the occurrence of silice in plants.

MATERIA MEDICA.
September 29.—Hours from 2 to 5 p.m.
1. What are the botanical and geographical sources of Asafoetida? State what you know respecting its collection, and describe its constituents.
2. In what plants does Caffeine occur? Give a method for its extraction, and describe tests for its identification.
3. What is Indigo? From what plant is it derived, and how may it be prepared.
4. How is essential Oil of Lemon prepared? Name and describe its chief constituents.
5. Discuss fully the official method for the estimation of Morphine in Opium, giving reasons for each step of the process.
6. Give the botanical sources and describe the physical and chemical characters of the following:—Berberine, Homatropine, Picrotinin, Thymol, Cathartic Acid.

CHEMISTRY.
September 29.—Hours from 10 a.m. to 1 p.m.
1. Write an account of the Periodic Law.
2. Discuss the analogy of nitrogen, phosphorus and arsenic.
3. Describe Racut's method of determining molecular weights. What special value does this method possess?
4. Show by equations what occurs when aldehyde is treated with—
   (a) Reducing agents.
   (b) Oxidising agents.
   (c) Ammonia.
   (d) Hydroxyacetic acid.
   (e) Sodium hydrogen sulphite.
5. State what you know about the isomeric forms of tartaric acid.
6. What are mercaptans? How are they produced, and what do they yield by oxidation?

PHYSICS.
September 29.—Hours from 2 to 5 p.m.
1. What is meant by the “critical point” of a gas? Describe some methods of liquefying gases.
2. Draw diagrams to illustrate the structure of the spectroscope. What are the ultraviolet and ultra-red rays, and how may their presence be recognised?
3. How would you determine the specific heat of lead?
4. Describe the construction of the balance, and show clearly how (a) accuracy and (b) delicacy are attained.
5. What is Ohm's law? What is the strength of the current passing through a wire having a resistance of 46 ohms connected with a battery of six cells arranged in series, the E. M. F. of each cell being 1.8 volts, and its internal resistance 7 ohms?

6. An electric current is passed successively through acidulated water, solution of cupric sulphate and argentite nitrate. When 15 C. of mixed gases have been evolved from the water, what weights of copper and silver were eliminated?

\[
\text{Cu} = 63.4; \text{Ag} = 108.

MEETING AT NEWCASTLE-ON-TYNE.

In response to an invitation from Mr. Barnard S. Proctor, Local Secretary of the Pharmaceutical Society for Newcastle-on-Tyne, a meeting of the chemists and drugists of the city and neighbourhood was held on Wednesday, September 26.

Messrs. B. S. Proctor, N. H. Martin, T. Miller, J. J. Daker, T. Maltby Clague, J. Rose, G. Hall, W. Giles, G. Weddell, G. N. Marsen, T. S. Herd, and P. Bell Kirkop were present. A letter regretting inability to attend was read from Mr. Wardroper, of Cullercoats. Mr. Proctor was elected chairman.

The first object of the meeting was to agree upon a gentleman to act as Local Secretary of the Pharmaceutical Society. Mr. Proctor having intimated that he would prefer to make way for a younger man. It was explained that the nomination would be made by the members and associates in business of the Pharmaceutical Society in the usual way, but that the suggestion of a preliminary discussion and agreement was made some time ago.

A conversation then took place on the subject. Subsequently the effect of the decrease in the revenue from stamped medicines was discussed on a list of figures brought forward by Mr. Weddell. Mr. Martin and the Chairman afterwards gave the meeting some interesting information as to the effect of recent decisions in the law courts as to the sale of poisons.

American Pharmaceutical Association.

ANALYTICAL ALKALOIDAL CHEMISTRY.

The Relative Value of Gravimetric Methods, Mayer's Reagent and Titration with Potassium Acid Phosphatid in Assaying Alkaloidal Drugs and Gallein Preparations.

By Lyman P. Kehler, Ph. C., B. S.

A century has nearly elapsed since the discovery of the first alkaloid, "morphium," by Sertürner, and yet how inefficient and unsatisfactory are the methods generally employed in our era for estimating these active principles.

The earliest methods devised for the detection and estimation of alkaloidal poisons in forensic chemistry were those found effective in removing the alkaloids from the inert matter associated with them in nature. The material was first extracted with dilute acids, aided by gentle heat, the gummy matter and other substances removed with lead acetate, excess of lead precipitated with hydrochloric sulphide, and the alkaloid obtained as an impure alkaloidal salt, generally an acetate.

Nearly all of the methods now employed are based on the principles of immiscible solvents introduced by F. J. Otto. In 1886, as a modification of J. B. StaY's method for the recovery of alkaloidal poisons ether was first so employed, then followed chloroform, then any [illegible] alcohol, and finally G. Dragendorff presented a comprehensive scheme for separation by solvents immiscible with water applied in both acid and alkaline solutions. The plan of separation was first published in pharmacopoeias, and more recently for the use of toxicologists, has been extended by chemists everywhere and in every direction, so that it has become the most convenient method of separating alkaloids for analytical work and manufacturing purposes.

Readous and comprehensive as some of the recognized methods based on the above principles of immiscibility, notwithstanding the results are frequently wide from the truth as generally arrived at gravimetrically. Not that the gravimetric part of the assay is deficient, for that portion of the process is recognized as the most reliable of all methods, but the extraction of inert matter through the agency of immiscible solvents prior to the weighing is the detrimental part. Extract the acid solution as long as you please with a given immiscible solvent, yet on rendering the solution alkaline there appears to be a certain constant amount of the material rendered soluble in the solvent employed. In some cases the quantity is inappreciably small, in others it composes the greater part of the alkaloidal extract. How to eliminate these foreign, not always inert substances, is a question frequently harrowing us. As types of the gravimetric processes containing this objectionable feature may be mentioned the methods of Lisch, Hager, Lyons, Lloyd, Thompson, Beckurts, Dietrich, etc.

It is not necessary to go into the merits and demerits of the methods, suffice it to say that each is favored with both more or less. Even the officially recognized method for assaying opium and opium preparations comes to share the spot in this direction, for as high as 2 per cent. of foreign matter has been found in some of the samples of morphia obtained by this process.

To be sure there are special methods for separating alkaloids in a state of purity as the introduction of Stolz's method bas principally on phosphaoptagistic acid and chloroform; another initiated by T. B. Groves using potassium iodide and an immiscible solvent; also a third method based on Sommenschewit's reagent, sodium phosphomolybdate, and an appropriate solvent. By employing these latter processes, we are enabled to secure a product of considerable purity, at no inconvenient loss however. Nor is this all, but these...
methods can be neither expeditiously executed nor economically employed in an analytical laboratory where many analyses are made daily.

The germ of a very important method was introduced by P. Boullé,* later announced by P. A. von Bonsdorff and F. L. Winckler† in the alkaloidal reagent potassium mercuric iodide. A. von Planta-Reichenäö reported the use of the tenth-normal solution of this reagent, substantially as presented in its practical form by P. F. Mayer.‡

Most alkaloids are completely precipitated from aqueous acid solutions by a solution of potassium mercuric iodide. It has generally been assumed that these iodomercurates consist of a double iodide of the base with mercury, but there is a great discrepancy between fact and theory when attempting to verify this general assumption. The precipitates are far from being constant, varying with the degree of concentration, temperature, manner of adding the reagent, and many other minor points. Titrations executed under the same conditions precisely, often vary appreciably from one another, although they give close approximations to the truth in some instances.

A point deserving especial mention in this connection is what may be termed an equilibrium; that is, a condition in titration of such a nature that, on addition of either the reagent or the alkaloidal solution, a further precipitation occurs.

In spite of the imperfections clustering around this method, it certainly extends to us a tempting short cut to arrive at comparative values of the various alkaloidal plants, and contains in it a step (titration) which introduces us to a truly scientific method; titration with volumetric acid solutions; which compensates Mayer's method in the region of quantitative values.

The employment of volumetric solutions in estimating the potency of alkaloidal plants is current with alkaloidal chemists abroad, and heartily sanctioned by many of our fellow-countrymen; nay, some have even expressed themselves publicly as to its being the only scientific and reliable method. It is to the latter that the writer would bring a word of encouragement.

For some time the author has been collecting data bearing on this point, which are expressed in the table above.

That this method is confronted by no obstacles no one claims; in fact, we frankly admit that several questionable elements enter it prima facie, and give reasons of doubt as to its absolute correctness. Taking these defects and calculating them at the utmost, we find ourselves nearer the truth than by the results obtained by the general gravimetric methods.

The first defect deserving of mention is our imperfect

† 1839, Ann. der Phys. Pogg., 93, 345.
‡ 1830, Buchner's Repertorium, 35, 57.
§ 1846, "Das Verhalten des Alkaloids gegen Reagentien," a dissertation at Heidelberg.

Note.—In answer to the query, With what drugs does the ferro hydroxy process give uniform results? I would say that all of the drugs in the above table gave me satisfactory results as a gravimetric process, excepting aconite leaves and sometimes the root, belladonna leaves, coca leaves, comum fruit, henbane, jabonari, and veratum viride.
knowledge of the molecular weights of several of the alkaloids, as emetine, aconitine, glycoside, etc. This deficiency is an indicator of their research, which will furnish us with the needed formulae. The second defect lies in this, that some of the drugs contain two or more alkaloids of different molecular weights, as vincristine, cinchona, aconite, etc. This compels us to assume that the alkaloids exist in a certain relative proportion in order to arrive at a molecular weight on which to base our calculations, and can be remedied only by determining by careful analyses the definite amount of each alkaloid.

When we reflect a moment on the advancement of the volumetric method represents all, with one accord precisely. The alkaloid represented by each titration is absolutely correct. A point in this connection should, however, engage our serious attention, and that is the method employed for extracting the alkaloid. One method is better suited for one drug than another, consequently we should endeavor to execute our work that each drug be thoroughly tested by a number of workers with simultaneous economical process, and that process giving the most uniform results, as well as the highest, should be the one adopted by all alkaloidal chemists. Mr. Karl Schwickerath has set us a most excellent example in the study of the "perforation method." The result will be that a preparation standardized in this way will have the same therapeutical strength as a similar article essayed in Maine. As it is at present, almost every analyst uses a different process for standardising and assaying a given drug, and the results are as variable as are the number of manipulators.

A single example serves to show the variability of the different methods with sufficient momentum to cause every diligent worker to reflect seriously. Fluid extract of belladonna leaves, with the gravimetric processes the variability ranged from 0.493 per cent to 0.461 per cent.; with the potassium mercuric iodide reagent from 0.781 per cent. to 0.758 per cent., and the volumetric method gave us from 0.253 per cent. to 0.214 per cent. The material was taken from the same bottle and all assays made within forty-eight hours of one another, with at least duplicates in every case.

In the table (p. 286) are given the maximum, minimum, and mean results of the majority of the practical gravimetric processes, Mayer's reagent, and volumetric acid solutions.

A short perusal of the results portrayed in the above table clearly reveals the desirability of a more uniform system of assayig the various alkaloidal plants and their preparations.

In titrating with volumetric acid solutions the indicator is one of the first factors to be called into requisition. The behaviour of the alkaloids with indicators presents some remarkable differences. Methyl orange can be used generally in titrating the alkaloids with mineral acids. Litmus and phenolphthalein are applicable to the strongly basic alkaloids, but are worthless for the feebler ones. Laeomoid has been employed by Van Itallie for titrating certain

alcaloids with hydrochloric acid, and E. Dieterich used rosollic acid, but his results leave the value of this indicator in doubt. O. C. Pfitzner has his extensive communications on the valuation of drugs employs hematoxylin as the indicator and hydrochloric acid for titrating. Brazil wood has recently been reported as very efficient, and adopted by the United States Pharmacopoeia of 1890 for titrating nux vomica and its preparations, but it has not found most efficacious in the writer's hands for all alkaloids.

In titrating with cochineal or methyl-orange it is seldom convenient to employ an aqueous solution of the alkaloid. A solution of the base in dilute alcohol is quite suitable, the indicators being very sensitive in its menstruated state for all alkaloids.

Occasionally the alkaloidal residue is abundantly contaminated with colouring matter, extracted with the alkaloid from its natural sources. In such cases the following ingenious method, due to A. H. Allen, is very useful. Dissolve the residue in a small quantity of ether, transfer the solution to a small glass-stoppers cylinder, add a few cubic centimetres of water coloured with the indicator. The standard acid solution is gradually added in drops and the solution will agitated after each addition. Under these conditions the end re-action is easily determined, for the colouring matter in the upper ethereal layer presents a strong contrast to the lower coloured aqueous stratum.

The principles of volumetric analysis are so well known that it seems quite unnecessary to give the method of procedure in detail.

The acid solutions found to give the most uniform and satisfactory results were twentieth-normal solutions of sulphuric and hydrochloric acids. The acid is added in slight excess, and titrated back with a centesimal normal solution of potassium hydroxide.

In conclusion, the writer would urgently recommend the adoption of a certain method for extracting the base or bases from each alkaloidal plant, and titrating the residue with a volumetric acid solution in order to obtain uniform results with every drug.

Society of German Naturalists and Physicians.

The sixtieth meeting of the Society of German Naturalists and Physicians, formally opened on Monday, Sept. 24, at Vienna, must be regarded as one of the largest and most interesting of recent congresses. Probably more than five thousand persons, ladies and gentlemen, took part in it, amongst them many of the leading lights of each of the forty sections into which the congress was divided.

No city in the world could offer such attractions for a visit of this nature as Vienna. Centrally situated, easy of access, replete with buildings of exquisite beauty, and possessing a university of world-wide reputation, it has no rival, as indeed the success of the congress proved.

On the occasion of the opening by Professor Kern von Marliann, the large hall of the Musikverein, in which the general meetings were held, presented a brilliant sight. The body of the hall was filled with members and visitors, the bright blue uniforms of numerous officers relieving the sombre black of the civilians, whilst the surrounding open

* 1893, Bull. Pharm. 7, 534, and 1894, Ibid. 9, 246.
* 1893, Van Loden Humanseb, Pharm. Centralhalle, 34, 391.
* 1897, P. C. Plagge, Arch. der Pharm. (3), 25, 49, and 49.
* 1894, Wochenschr. f. Chem. u. Pharm., 32, Nos. 6, 7, 8, and 12.
boxes were assigned to the ladies. Unfortunately, the size of the hall, and possibly also defective acoustic properties, rendered the speakers inaudible to the majority of those present. After the conclusion of the opening ceremony, and the delivery of addresses by Professor Leydes (Berlin) and Professor E. Mach (Prague), sectional meetings of the diverse forty sections into which the Congress was divided were held in the lecture theatres of the University or other institutions.

In these sections, the two of most interest to pharmacists were No. 20 (Pharmacology and Pharmacognosy), and No. 21 (Pharmacy). Seldom has pharmacy been more worthily represented. To prove this it is but necessary to mention such names as Beckurts, Fröhlich, Hanasek, Hartwich, Hellman, Martensen, Moeller, Schär, Schmidt, Waldheim, Techirch, and Vogl. In the former of the two sections Professor Vogl was elected chairman, and proceedings at once commenced by a paper by Dr. Gottlieb on the physiological action of the various tropine, iatro tropine alone possessing the author the characteristic action of atropine.

Professor Schär's next subject was the structure of genuine and false cubeas, and drew attention to the admixture, apparently accidental, of the root of Cypripedium pubescens with hydrastis and with serpentina. The remaining papers announced in this section being of purely pharmacognostical interest the section amalgamated with No. 21 (Pharmacy).

In this department Professor E. Schmidt (Marburg), who had been elected chairman. Professor Schär, in a paper on tincture of guaiacum, considered it a valuable reagent if properly used. Professor Beckurts (Brunswick), recognising the importance of the subject, discussed the methods of assay of nemorica, belladonna, henbane, stramonium, cnicum, ipecacuanha, and their preparations; the proceedings in this section terminated with a paper by Alois Kremel (Vienna) on beeswax, in which the author insisted on the inefficiency of Hübli's acid and ester numbers alone, and the necessity of applying other tests, such as specific gravity, etc.

Most of the members of the section and many others were present the same evening in the hall of the Lower Austrian Gewerbe Verein, in which Professor Techirch showed and explained a series of about a hundred lantern slides illustrating his travels in Ceylon and some of its medicinal plants. At length the meeting was closed by the Verein attracted much attention.

The second meeting of the section Pharmacy was held in the museum of the Apotheker Verein, and combined with a meeting of that society and the Hauptpreis. To the uninitiated the object of this arrangement was soon demonstrated by an eloquent speech delivered by Professor Techirch, emphasising the services which had been rendered to pharmacognosy by Professor Vogl (Vienna), and tendering him, in the name of the committee he represented, the Flickiger medal. After the appropriate follow-up to this presentation had subsided, Professor Vogl responded.

Professor E. Schmidt (Marburg) then discussed the relations existing between atropine, hyoscynamine, and scopolamine, maintaining the non-existence in henbane seed of an alkaloid of the formula C19H24NO2. He also discussed the relation in which corydine stood to berberine.

Professor Techirch (Bern) followed with a paper on "Secretions," summarising the results obtained in his laboratory in investigations on the chemical constitution of these bodies, and asserting that the fluids take place in a particular layer of the cell wall, and in that layer alone. Professor Techirch also explained the course of germination of the nutmeg. Storax was considered by Professor Moeller (Gras) to be a pathological product, as it was not contained pre-formed in the bark, nor could it be obtained by incision. Gentle beating was followed by formation of the balsam.

Professor Hartwich (Zürich) showed two so-called "false" cinchona barks, the one he referred to Ladenbergia magnifolia, the other being probably the bark of a sapotaceous tree.

These proceedings concluded the morning sitting; in the afternoon the Viennese pharmacists gave a demonstration of their skill in the form of a dinner, at which the President of the Apotheker Verein, Herr v. Waldheim, presided.

On Wednesday a second general meeting was held, during which lectures were delivered by Professor Klein (Göttingen), Professor Forel (Zürich), and Professor Boltzmann. In the afternoon the section Pharmacy again experienced Viennese hospitality in the form of a dinner given by the Austrian Pharmaceutical Society under the auspices of its President, Dr. Hellmann (Vienna). As on the previous day, the enthusiastic reception of the toasts and responsive speeches could not leave in the most superficial mind a doubt of the spirit of the reception accorded to the visitors. Thursday was devoted entirely to business. Professor Schär (Zürich) described the structure of the bark of Fouqua sperens, and showed the seat of the wax, ocotilla wax, which it yields. Dr. Schachner (Vienna) adduced figures in support of Flickiger's opinion as to the seat of the bark, which, in which case, however, he found a vigorous opponent in Eugen Dieterich (Hellenberg). The latter had analysed a large number of samples of opium from the museum of the Pharmacological Institute (Vienna), and communicated the results. Dr. Jolles (Vienna) discussed the discovery of sugar in urine, whilst Dr. Schrank (Vienna) spoke of the probable influence of bacteriology of pharmacy. Anton v. Waldheim (Vienna) pointed out the progress towards internationality shown by the latest editions of various pharmacopoeias. Dr. Kwikzla compared at length the tests adopted by the German, Austrian, Swiss, and other pharmacopoeias for certain bodies. After the last paper had been read the meeting was declared closed.

Beyond these meetings and functions, which were exclusively pharmacetical, the members availed themselves of the invitations issued to the members of the Verein and catered for at Court by the Archduke Carl Ludwig, and at the Rethaus by the burgomaster, Dr. Raimund Grüb. If the honour of the former be greater, yet the geniality of Dr. Grüb's reception charmed all visitors. The ladies on this occasion were presented with bouquets, the gentlemen with cigar cases containing cigars and cigarettes. Nor was the inner man forgotten. If it were possible to have been fatigued by the inspection of that beautiful building, provision was made for the possibility by refreshments of most varied nature.

The last general function was the excursion to Semmering on Saturday, September 29. About 400 of the visitors were conveyed by special train to Semmering, where the day was spent in excursions under the guidance of members of the local Alpine club. The exquisite scenery and the interest attached to the mountain railway rendered the excursion a most enjoyable one.

During the whole of the Congress most of the public buildings, institutions, museums, and the like were open to inspection by the visitors. The facilities thus offered to strangers contributed largely to the success of the meeting, and to the pleasure of those fortunate enough to take part in the Congress. For its meeting-place next year the Society has decided upon Lübeck.

POISONING CASES AND INQUESTS.

PECULIAR DISPENSING BY A MEDICAL MAN

An inquest was held at Hatching on September 28, respecting the death of the infant daughter of a machine minder named Batten. The child being ill from bronchitis the mother took it to Dr. Scott’s surgery and got a bottle of medicine. When she arrived home she gave the child a dose, and shortly afterwards the doctor called and said he had made a mistake in the mixture. The child was attended by the doctor during the day, but she died. At Coroner Wyatt’s inquiry the father said he believed Dr. Scott did all he possibly could for the child, and Dr. Scott said the baby for bronchitis a short time back. When the mother called on Tuesday he was mixing a lotion consisting of acetic and morphine in a large graduated glass which he usually kept for water. Witness put the glass on the counter, and, taking a bottle, placed therein the necessary drugs. Having done so, he mechanically took the glass containing the poison and filled up the bottle. Almost immediately the woman had left he discovered the mistake. As he had not the name of the parents on his book he went to Mr. Hobman, the proprietor of the estate, and from him ascertained the address. Upon arriving at the house he was informed by the mother that she had given deceased a dose. The usual remedies were resorted to, but deceased gradually became comatose and died. He was a fully qualified medical practitioner. The bottle was a 1/2 oz. one, and the lotion he put in it in mistake for water contained about a third of a grain of pure morphone. He saw deceased about twenty minutes after it had taken the dose, and did all he possibly could to save its life.

The Coroner: It’s a very sad case, but in my opinion there was no carelessness. Dr. Scott has not attempted to shield himself in any way, and he has given his evidence very straightforwardly.

The jury eventually returned a verdict of "Death from misadventure." Morning Leader.

POISONING BY WEED-KILLER.

At Bathgate, September 23, Robert Gibson, seven years of age, residing with his parents at Academy Street, Armadale, died under peculiarly painful circumstances. The boy’s father had recently been on a cycling tour to Berwickshire, and, his machine having required oil, he obta a poisonous weed-killer from his brother-in-law in mistake for machine oil. Some time afterwards the brother-in-law discovered his mistake, and warned Mr. Gibson to destroy it at once. It seems that the father forgot to do so, and on Friday the boy had some liquorice, and while looking for a bottle to make some liquorice juice, he came across the one containing the poison. Thinking it liquorice juice he drank some of it, and not till twenty minutes afterwards told his mother, who immediately sent for Dr. Anderson, who applied the usual emetics without avail. Glasgow Evening Times.

POISONING BY A PLATINUM SALT.

On Friday, September 21, Mr. L. R. Rowbottom, Coroner, held an inquest at the Infirmary, Wigan, into the death of a child named John Varey, who died on Wednesday from the effects of taking a quantity of platinum, which was administered in mistake for teething powder.

The Coroner explained that Inspector Williamson being away he had made enquiries into the case himself. The mother of the child went to Mr. Atherton’s shop in Market Street to obtain some teething powder for her son, who was seven months old, and some insect powder. It seemed that almost at the same time a customer had purchased a preparation of platinum for photographic purposes. He bought eight grains, for which he paid a shilling, the value of the preparation being about £10 per ounce. It was made up in a parcel exactly similar to those which contained the teething powder and the insect powder. On putting the powders into her pocket the woman picked up the platinum that had been purchased by the man. The latter came back to the shop and said "I have lost my parcel." He bought another shillingworth, obtaining the last eight grains they had in the shop. When the woman got home she gave what she thought was the teething powder to her child, and after she fell ill she feared she had given the child that which she did not know she had, and which she never intended to purchase. The question came as to the sale of drugs and poisons. The platinum was not scheduled as a poison under the Pharmacy Act, and the chemist, who did not sell it to the mother, did not know it was poison.

Dr. R. S. Hardman, junior house surgeon at the Infirmary, said the deceased was admitted to that institution about ten o’clock on Tuesday night. He was then in a state of collapse, and was suffering from symptoms of intestinal irritation. He immediately suspected poison, but did not know what kind. He inquired from the parents, and was told that a wrong powder had been given in mistake. Death took place a few hours after admission. He had since made a post-mortem examination. Externally the child was fairly well nourished. Internally all the organs were healthy, except that there were enlarged glands in the abdomen and evidence of intestinal disease. There were traces of mineral poisoning, and in witness’s opinion death was due to that. Platinum was almost unknown as a drug. It had not been experimented with, but witness had been informed by a Fellow of the Chemical Society that the amount given to the deceased would be sufficient to cause death. A verdict of "Accidental death" was returned. Wigan Examiner.

POISONING BY HEMLOCK.

At Greenock, on September 30, two children, named William and James Harkness, aged eight and six years respectively, were accidentally poisoned by eating hemlock. It appears that the boys were removed in an unconscious state to the Infirmary, where they made ill once and then transferred by the house-surgeon, who stated that they were in a dangerous condition. Later, however, both children were declared to be out of danger. Greenock Telegraph.

FATAL DOSE OF SYRUP OF HYPOPHOSPHITES.

On Tuesday, September 18, at Burslem, George Pattison was found dead, showing symptoms of strychnine poisoning. A bottle of compound syrup of hypophosphites, which was produced, had been given to deceased by a fellow-lodger, who said he had warned deceased that the bottle contained death poison to cause death. The following morning the bottle which had contained the syrup was found empty after the deceased had left home. The jury found that death was caused by an overdose of the syrup, taken whilst of unsound mind.
PROCEEDINGS UNDER THE SALE OF FOOD AND DRUGS ACT.

WHAT IS SODA WATER?

Rodolph Gaunt, wholesale chemist and druggist, of 221, Union Street, Borough, appeared before Mr. Slade to answer a summons, taken out at the instance of Inspector First, the appointed officer to the St. Saviour's District Board of Works, under the provisions of the Sale of Food and Drugs Act, for selling an article, the same not being of the nature, substance, or quality of that demanded. The inspector sent his assistant into the defendant's shop, and under his instructions he purchased a syphon of soda water. The bottle containing the liquid was handed to him, and was analysed, and was found to be practically aerated water, there being no trace of bicarbonate of soda, whereas according to the formula of the Pharmaceutical Society (sic) it should have contained 30 grams. The officer pointed out that the real article was often required for medicinal purposes, and on that ground alone care should be taken to supply what might be required. The defendant said his firm had been carrying on business uninterruptedly for over sixty years, and this was the first time complaint had been made against them. As a matter of fact soda water supplied by the pharmacopoeia instructions was unpalatable, but if required for medicinal purposes it should be asked for as "B. P.". Mr. Slade said it was clear that the article sold to the inspector contained no bicarbonate of soda, and was not therefore soda water. He fined the defendant £3 and 12s. 6d. costs.—Morning Advertiser.

CORRESPONDENCE.

BRAGANTIA WALCHII.*

SIR,—Will you allow me, with reference to Mr. Hooper's paper on Bragantia (ante, p. 231), to mention that Dr. Solereder has shown that the stem I received under the name Bragantia wollichii cannot belong to that genus, nor even to the Aristolochiaceae. Dr. Solereder's paper is entitled "Beiträge zur vergleichenden Anatomie der Aristolochiaceen," and is contained in Engler's "Botanische Jahrbücher," x Band., 4 heft., p. 410, 41, Wellington Street, W.C. MAXWELL T. MASTERS.

OBITUARY.

Notice has been received of the death of the following:

On September 16, Henry Thurlow, Chemist and Druggist, Ixworth. (Aged 56.)
On September 20, Samuel Wilson, Chemist and Druggist, Ashton-under-Lyne. (Aged 59.)
On September 22, John James, Chemist and Druggist, Liverpool. (Aged 48.)
On September 24, Tom Fletcher, Chemist and Druggist, Leeds. (Aged 62.)
On September 28, Thomas Watkinson, Pharmaceutical Chemist, Nottingham. (Aged 72.)
On September 29, Matthew Hall, Chemist and Druggist, Newcastle-on-Tyne. (Aged 57.)

BOOKS, ETC., RECEIVED.

DIARY OF THE WEEK.

TUESDAY, OCTOBER 9.
Royal Photographic Society, at 8 p.m.
Presentation of Medals and President's Address.

WEDNESDAY, OCTOBER 10.
British Pharmaceutical Conference, at 9.30 p.m.
Meeting of the Executive Committee.
Pharmaceutical Society of Great Britain.
Library, Museum, School, and House Committee.
Plymouth and District Chemists' Association.
Annual Meeting at the Foresters' Hall, at 2.30 p.m.
Annual Dinner at Matthews' Restaurant, at 7 p.m.

THURSDAY, OCTOBER 11.
Chemists' Assistants' Association, at 8.30 p.m.
Musical and Social Evening.
Sheffield School of Pharmacy, at 8 p.m.
Inaugural Meeting at the Cutters' Hall. Address by Mr. Charles B. Allen.
Sheffield Pharmaceutical and Chemical Society, at 7.45 p.m.
Annual Dinner at the Cutters' Hall.
Nottingham and Notts Chemists' Association, at 8.30 p.m.
Soiree at the Eagle Restaurant.
Liverpool Chemists' Association, at 7.30 p.m.
Conversations at the Royal Institution.

COMMUNICATIONS, LETTERS, ETC., RECEIVED FROM MESSRS. Bayley, Buck, Clarke, Clarkson, Cocks, Cross, Flux, Grace, Griffiths, Hill, Jewsbury and Brown, Jones, Macnaught, Marshall, Smith, Squire.

* This name does not appear on the Register of Chemists and Druggists for 1894.
ANTI-DIPHTHERIC SERUM.

The immunity of individuals against disease is understood to depend upon the destruction by certain agents of the supposed living cause of the disease. These agents may also act by hindering the growth of the living cause or by destroying its infectious properties, by the destruction of the poisonous material produced in the infected organism, or by impairing a higher resisting power against the action of this poisonous material. Belief in the theory of phagocytosis—according to which certain cells of the body tissues possess the property of collecting about the infected region of the body and destroying by absorption the living bacteria supposed to cause the disease (see Pharm. Journ., vol. liii., p. 307)—has been in great measure replaced by the assumption that the specific action of bacteria is due to toxalbumins or similar poisonous substances. These "toxinas," as well as "antitoxins" or substances that establish immunity to specific diseases in animals, have been shown by Buchner to be probably the direct products of bacterial cells (see Pharm. Journ., vol. liii., p. 352).

The treatment of disease by prepared blood serum is based upon the foregoing ideas with regard to immunity, and is now being very extensively adopted. In April, 1893, Behring and Kössel published the results obtained in the treatment of thirty cases of diphtheria by the injection of so-called antitoxin serum. This serum was obtained from the blood of animals rendered immune to the disease by the prolonged injection of minute but gradually increasing quantities of diphtheria toxin, a fluid obtained by the cultivation of diphtheritic bacilli in nutrient broth. The success of the treatment, according to Behring and Kössel, was very remarkable, and more recently other observers— notably Ehrlich, Wassermann, and Roux—have confirmed their results.

The first step in the practical application of the process given in outline above is the preparation of the diphtheria toxin from cultures of the specific bacillus of the disease. Flasks containing nutrient broth are inoculated with the bacilli and maintained for several weeks at a temperature of 37°C. At the expiration of this period of incubation the contents of the flasks are filtered through a Chamberland filter, which arrests the bacilli. An illustrated description of this filter, as employed by d'Arsonval, will be found in the Pharmaceutical Journal (vol. liii., p. 1034). The clear filtrate thus freed from organisms has a strong alkaline reaction. It is a virulent poison, and speedily causes death when injected into animals in comparatively small quantities: from this property it is called diphtheritic toxin. The toxin is injected into animals in minute but increasing quantities at intervals extending over several months; the initial doses being so small as to cause only transient symptoms, and it is found that animals so treated are finally enabled to withstand the injection of such doses as would prove rapidly fatal to an un inoculated animal of the same weight. When the animal has been thus rendered immune, its milk and blood serum are stated to possess the remarkable property of protecting other animals from inoculation by the disease.

In order to obtain the serum, blood is withdrawn from the body and allowed to stand. It coagulates in a short time, the clot being composed of filaments of fibrin enclosing the blood corpuscles, and by the contraction of the clot the blood is separated into clot and serum, the latter being a pale clear fluid comprising practically the fluid part of blood, minus corpuscles and fibrin. The serum obtained in this way, from the blood of animals rendered immune, as previously described, constitutes the "antitoxin" used in the treatment of the disease, the name being derived from its antagonistic action to the "toxin" produced by the bacillus. It may be well to state here that nothing is known as to the nature of the substances to which the action of the toxin and antitoxin is due. From experiments on animals, the following results were obtained: (1) by mixing the antitoxin in certain proportions with the toxin in a test-tube, the latter is rendered harmless; (2) by first injecting the antitoxin, followed by the toxin, the same effect is produced; and (3) the toxin may be injected first, followed by the antitoxin: in this case a relatively larger quantity of antitoxin is required, and the interval between the injections must be brief.

The serum used in most of the cases reported was obtained from the horse. The animal is rendered immune by repeated injection over a period of two or three months, at the expiration of which its serum possesses very high antitoxic properties. The animal suffers in health but slightly if at all, and the operation of bleeding may be repeated two or three weeks after being first performed. It is even said to be possible with this animal, rendered immune as previously described, to withdraw about a kilo. of blood at once, and to repeat this from time to time, without any deterioration of the antitoxin obtained or danger to the animal, provided the injections of toxin be continued in the intervals between the blood-letting operations. The dog, goat, and sheep have also been employed, but the blood of the horse furnishes a more abundant and clearer serum than that of the other animals mentioned.

In the clinical application to diphtheria of this antitoxic method of treatment particular stress is laid upon the necessity of injecting the antitoxin as soon as possible after the onset of the disease, most successful results being obtained within twenty-four hours. After this the protective effects of the antitoxin diminish rapidly, and at an advanced stage of the disease disappear altogether. The effects of the injection in diphtheria are almost immediately manifested in the reduction of temperature and pulse to the normal condition, and complications which usually follow the recovery by ordinary treatment are said to rarely occur in cases cured by the antitoxin treatment.

* The terms "toxin" and "antitoxin" are here applied generally to the liquids containing the active agents, and not specifically to the latter.

Vol. LIV. (Third Series, Vol. XXV.), No. 1265.
The dosage of the remedy is at present in rather an unsatisfactory condition, due, of course, to the lack of knowledge concerning the nature of the bodies to which the toxic and anti-toxic effects are due. Standardisation of the antitoxin therefore depends on the results of physiological experiments. Various systems of stating the strength of the serum have been proposed by Behring, Ehrlich, and Roux. These depend essentially upon the determination, in the first place, of the lethal dose for an animal, such as the guinea-pig, of known weight, of a toxin solution which has been prepared in sufficient quantity to form the standard for a large number of cases. The quantity of antitoxin which must be previously injected to protect the animal against this lethal dose is then determined, and the ratio between the weight of antitoxin and the body-weight of the animal furnishes a means of representing in certain units the strength of the solution. Thus, a sample of antitoxin may be said to have a strength of 50,000 when an animal is protected against its minimum lethal dose of toxin by the subsequent injection of $\frac{1}{1000}$ of its body weight of the antitoxin in question. The best quantity to use for a case of human diphtheria must ultimately, however, be determined by experience. About one-tenth of the full dose is said to be sufficient for prophylactic measures, and about one-fourth serves to arrest the progress of the disease in its incubation stage.

The numerous results which have been published seem to indicate considerable variation in the strength of the antitoxin supplied by different makers, the quantities injected varying from 0.5 to 20 cubic centimetres. It is to be hoped, therefore, that some means will be found before long of producing the antitoxin of definite and uniform strength. The antitoxin manufactured under Professor Behring's supervision is supplied in two strengths: No. I. in tubes containing 10 c.c., sufficient for the treatment of cases of ordinary severity occurring in children; No. II. is about 25 times stronger than No. I., and the tubes contain 11.5 c.c. The latter is recommended for the treatment of adults or cases of exceptional severity in children. The antitoxin prepared at the Pasteur Institute is injected in doses of 20 c.c., one dose being usually sufficient.

Expectations are entertained by some investigators that other diseases, such as cholera, pneumonia, and tuberculosis, will also prove amenable to the same system of treatment. Tetanus has already been treated, but the course of the disease is so rapid that in only a few cases has an opportunity been afforded for the application of its specific antitoxin.

It is obvious that the preparation of these antitoxins is altogether beyond the range of pharmacy in this country, on account of legal restrictions. With regard to their preservation, the addition of some harmless antiseptic would probably be found necessary, and in handling the preparations pharmacists must adopt precautions similar to those employed in dealing with ordinary vaccine lymph, such as storage in a cool, dark place, with the least possible exposure to atmospheric influence, but still greater care will probably be requisite than in the case of lymph.

Practical Systematic Botany.

This branch of botany can be most advantageously studied during apprenticeship, for when a course of study at a school of pharmacy is begun, the pressure of work is usually so great, and time is so limited, that wasted hours and neglected opportunities are looked back upon with regret.

The minimum requirements of pharmacists' students in systematic botany comprise a knowledge of the classes and sub-classes of plants, and of the distinctive characters of forty-one medicinal plants. Later on, an acquaintance with about twenty-eight natural orders and seventy of the principal genera is necessary.

It is not suggested for one moment that this is all that is required in botany, but it is merely desired to point out here that morphological and systematic botany may be advantageously studied during apprenticeship, so as to economise the limited time that can be given to the whole subject during the usual year's course of study before qualification, and to leave more time for the study of vegetable histology and physiological botany, in which the help of a teacher is more especially needed.

The best time to study plants is undoubtedly during the spring and summer months, from April to September. These months, during the first year of apprenticeship, may be devoted to the examination, comparison, and naming of the different parts of plants, commencing with such indigenous medicinal plants as are procurable. For instance, a collection may be made of leaves of different forms, arranged side by side for comparison. These will be available for subsequent microscopic work if required. When these are mastered, a similar collection of flowers and inflorescences may be made, and so on, passing through all the parts of a plant. A little practice will soon show how difficult it is to define exactly the shape of a leaf, and how various terms must be combined to convey an accurate idea to the mind of any leaf, flower, or inflorescence, etc.

The best plan to adopt in making such collections is to follow a chapter in a text-book on botany* and collect all the forms mentioned in it that are available, or a glossary in which the terms applied to each organ are collected together. For this purpose Holmes 'Botanical Note-book' obtainable from Dulau and Co., London, will answer admirably.

When the principal names applied to the variations in the different organs of plants are understood, the next step is to attempt to describe a plant. For this purpose indigenous medicinal plants should be first chosen, as the description can be subsequently checked by the description given in the Pharmacopeia or in a Flora. The schedules in the 'Botanical Note-book' mentioned will be found a useful guide as to the method of describing a plant. There are sixty schedules given, and by the time these are conscientiously filled up, the glossary will have been gone through sixty times.

* Some of the most portable and convenient books for this purpose are Silver's 'Outlines of Botany' (Renshaw, 30s, Strand), an old but very useful book; Bentley's 'Student's Guide to Structural, Morphological and Physiological Botany' (Churchill); Lindley's 'School Botany' (Bradbury, Agnew and Co.).
and the student who has not by that time acquired a familiarity with the meaning of the terms employed is never likely to do so. The power of remembering the terms used will depend somewhat upon whether the student possesses a knowledge of Greek or not, since many of the terms are derived from that language. If he has not he should pay particular attention to the derivations of the names and their meaning given in the glossary, since many of the same Greek words also occur in chemistry. The mastery of this branch of the subject is absolutely necessary to further progress. As the carpenter by frequent use of his tools gets to understand their uses and capability, so the student must use botanical terms often, if he wishes to have a clear conception of their meaning. It is not sufficient to read about them or even to learn them by rote. He must see the things to which the names apply. The writer has known students who, having an excellent memory, could give a parrot-like definition of almost any botanical term, but could not recognize the parts they had described when shown to them. There is no more effectual way of learning botany than by examining the plants themselves and attempting to describe them.

When the power of describing a plant in ordinary botanical language is acquired, which should be by the end of the second September, the third summer may be devoted to classifying plants.

Here a word of warning is necessary. If progress is to be made, and mistakes and pitfalls avoided, a definite rule must be invariably followed. The class must first be determined, then the subclass, and lastly the natural order. Any attempt to guess at the natural order before going through the preliminary examination as to class and subclass is sure sooner or later to lead to mistakes and waste of time. The "short cut" will prove the long way round. Exception to rules in classification, of course, occur, but they are comparatively few. If cases are included in the book already referred to, but in any case of real difficulty the "Notes and Queries" column in this Journal is available for help.

The study of the natural orders may be commenced somewhat in the following manner. A number of different plants are collected, with fairly conspicuous flowers, and a few ferns. The specimens may then be sorted out into three parts: 1st, in which the leaves have the small veins forming a network, as in the hazel; 2nd, in which the veins are parallel, as in grass, lily, or iris leaves; and 3rd, in which they are forked, as in ferns.

If the flowers of these groups are examined, it will be found that the plants with the reticulated veined leaves have the flowers, with a few exceptions, arranged in rows of five parts or a multiple of five: or in rare cases, by suppression of one part, the number is four. The plants with parallel-veined leaves will have the parts arranged in rows of three or a multiple of it, and the ferns will have no visible flowers. These three groups form the principal divisions of the vegetable kingdom, and it is absolutely necessary, as a first step, to determine to which of these groups any plant belongs. The student may next cut thin transverse sections of the stems of each group and examine them on a dark surface, such as a coat sleeve, with a good lens, preferably a microscopic one, or a 1-inch objective from a microscope. He will find in the plants having reticulated veined four or five parts to the flower, that the section of the stem will show a central pith with a definite ring around it (dicotyledon). In the stems of the plants with flowers in three parts he will find that the sections are dotted over with whitish points (of woody and vascular tissue—monocotyledon), but that there is no definite pith with a ring outside it, and in the fern he will find that there is an irregular ring (acotyledon). By this test he will always be able to determine to which class a plant belongs, if the flowers and leaves should seem anomalous. Thus, in some of the docks (Rumex) there are net-veined leaves and three-parted flowers, but the stem when cut shows the woody ring outside the pith. On the other hand, in the black bryony (Tamus) the flowers are also three-parted and the leaves reticulate-veined, but the stem section shows the woody tissue in scattered dots, indicating at once that the two plants belong to different classes, although similar to each other in the character of the leaves and flowers.

(To be continued.)

PHOTOGRAPHY AND ITS SCIENTIFIC APPLICATIONS.*

BY SIR HENRY TRIPHAM WOOD.

It is not so very long since photography occupied a very subordinate position in the world alike of science and of art. Scientific men looked on photography as a mere art, artists regarded it as a mere science. About twenty years ago, when I suggested that some improvement in a photographic process—I forget now which—ought to be brought before the Physical Section of the British Association, I was told that there was nothing scientific about photography, that it was a mere empirical pursuit, unworthy the attention of serious students of science.

And to a large extent the reproach was well deserved. Though the list of the earliest workers in photography contains many illustrious names, yet it is true that a large proportion of the most important contributions to photographic knowledge were not made by scientific workers, or by men who worked in scientific methods. They were obtained by practical men, seeking for results, often indeed seeking for them successfully by methods which could not have commended themselves to men better equipped with scientific knowledge. Of course this was the consequence of the fact that photographic science was early associated with photographic practice, and the same remark holds good of other sciences, electricity for instance, in which theory and application to practical use advance with equal steps; but I think it applies more to photography than to any other.

At the present time, we have indeed reached a very different condition of things. All the most striking of

* The meaning of botanical names may be found in Cookes' Manual of Botanic Terms (Hardwicke), and Alcock's Botanical Names for English Readers (Lovell, Reeve and Co.).

* Extracted from the presidential address to the Royal Photographic Society, October, 9, 1894.
the recent advances in the science are the result of elaborate scientific research. The most recent improvements in lenses were the fruit of long and laborious investigation into the optical properties and the chemical nature of certain sorts of glass. The increased speed of modern plates, and their improved power of rendering colour values more truly, have only been obtained by minute knowledge of the condition of the problem to be solved, and by careful application of the most recent results of chemical and physical research. If the old photographic process, the reproduction of colour, has been solved, or, at all events, if a possible method has been indicated for its solution, it was not by haphazard experiment, but by careful adjustment of means to secure an anticipated result. Nowadays, we can only hope for improvement by utilising the advance of scientific knowledge.

But if the present position of photography is due to progress in the kindred sciences, how amply has she repaid the debt! There is not a single branch of science in which photography is not largely used. There are many whose progress is now absolutely dependent on the power of the camera to observe more accurately, more independently, more minutely, more rapidly, more permanently, than the human eye. If, as appears to be the case, we have reached the limits of human vision, aided by the most delicate instruments that can be constructed, it is difficult to imagine what limits need be set to photographic vision, can we but construct instruments of accuracy sufficient to allow its full powers to be utilised.

I imagine that the first application of photography to a scientific purpose must have been when Dr. Draper, in New York, photographed the moon. Whether the pictures he obtained were of any astronomical value I do not know; certainly those taken a little later, in 1852, by Dr. Warren de la Rue, were, and they were the precursors of the long series of astronomical photographs, culminating in Dr. Common's nebula of Orion, and in the great work of charting the heavens by photography which is now in progress.

The advantages of the "retina which never forgets," and it might be added which never tires, which accumulates weak impressions and stores them up till they become one strong one, were long since recognised by de la Rue, and I suppose it will not be very long before, for astronomical purposes, eye observations are entirely superseded by photography. The photographic camera is now an indispensable adjunct to every large telescope, if indeed it would not be equally correct to say that the telescope is an adjunct to the camera, since the astronomical telescope tends more and more to assimilate to the form adopted long since by Mr. Rutherford, in which the visual rays are of but slight importance, and the chief attention is given to the accurate utilisation of the more chemically active rays at the violet end of the spectrum.

In his recent address to the Photographic Convention at Dublin, Sir Howard Grubb, than whom nobody is better qualified to speak on the subject, dwelt on the services which photography has rendered to astronomy, and gave several striking illustrations of those services. Indeed, if one not qualified to speak on such matters with any authority might hazard an opinion, it would almost seem as if the power of recording observations had already outstripped the capacity for examining the observations, and drawing conclusions from them. When we are told that a photographic plate has recorded 10,000 stars in an area not containing a single visible star, one may be excused an expression of wonder as to how the human mind is ever to grapple with problems of such infinite complexity, to turn to useful account observations dealing with such enormous multitudes.

But if the telescope has lately become one of the most important of photographic appliances, the spectroscope may be said to have held that position almost since its introduction. Professor Norman Lockyer, in his well-known text-book, attributes to Sir John Herschel the first suggestion of spectrum photography, and we find that in 1839 he pointed out that the way to investigate sensibility was to photograph the spectrum. In the following year he read a paper describing his results of spectrum photography. A little later, in 1842, Becquerel and Draper were both at work photographing the solar spectrum. Twenty years later (in 1864), Miller was turning to practical account the power of photography to record the parts of the spectrum beyond the limits of human vision, and from that date nearly all spectroscopic work has been photographic work. Whether applied to astronomical observation or chemical research, the spectroscope has always been combined with the camera, and it is by the combination of the two instruments that such wonderful results have been attained; and as photographic methods have improved, so have fresh facilities been afforded to the spectroscopic worker. Norman Lockyer's earlier work was of necessity done with wet plates, but with the plates now available, he is producing star spectra on a scale comparable with the solar spectra of twenty-five years ago. Rutherford's recent maps of the solar spectrum could not have been produced without the use of colour-sensitive plates; while in one of the most recent attempts to employ spectroscopic analysis for practical metallurgy, Professor Hartley tells us that he also used orthochromatic plates, specially prepared, and that after trying various developers, he found hydroquinone the best.

As an automatic recorder of scientific observations, photography seems to have been utilised in the Royal Observatory about 1847.

The principle thus first applied at Greenwich has received numerous other applications, and, indeed, it is now a matter of course that photographic methods should be used to register the movements of any instrument of whose indications it is desired to preserve a record. Instances are of course numerous in which no other method is possible. Hardly any but a photographic method could register the movements of the light spot of a reflecting galvanometer and thus enable the physicist who, like Langley, is measuring the heat radiated from celestial bodies, to record the minutest differences of temperature; the chemist, like Dewar, who is producing hardly imaginable cold, to record temperatures approaching absolute
zero; the metallurgist, like Roberts-Austen, who is dealing with the melting points of metals, to register by a photographically traced curve variations in high temperatures which, but a short time ago, could not be accurately measured at all. It is interesting to read the testimony of the last named, given at the last Conference of the Camera Club, to the effect that he could not conceive of any method which would give such results in the same space and time. Equally interesting is it to note the professor's suggestion for a practical method of recording continuously the temperature of the air-supply of a blast furnace, a matter of great importance to the iron manufacturer, of which he says:—"If we had no photography it would be impossible to get a record which would be anything like so true."

Numerous other instances will occur to many of you in which photography has been or might be—indeed I may say will be—applied to similar purposes. I will only refer to one, because it appears to me so excellent an instance of the delicacy of the method. At the last, the Oxford, meeting of the British Association, Mr. Burch showed to the newly-formed Physiological Section photographic records taken with the aid of the capillary electrometer of electric currents produced by speaking into the telephone. The letter z produced a complicated curve in which oscilations of current lasting only 1-8000 sec. were visible with a lens.

It seems hardly worth while to trouble you with the details of many of the other services which photography has rendered to science, and if I were to attempt an exhaustive list, there are many present to-night who could supplement it out of their own knowledge. The meteorologist has been enabled by its aid to study the form and nature of clouds, the shape and character of the lightning flash. The zoologist has been taught much about animal motion. The microscopist has long learnt to rely on the camera as the only accurate means of reproducing the objects of his studies. The physiologist has by photographic methods investigated many phenomena in which the changes are too rapid for the human eye to follow them. By such means Lord Rayleigh and Professor Boys have obtained long series of pictures of occurrences which all took place within a fraction of a second, thus almost analysing time as the chemist analyses matter.

The uses of photography in ethnology, geology, geography, natural history, archæology, are too obvious to need mention. They, and many other applications, may be summed up in the remark, that whenever the observer of natural phenomena requires to make an accurate record of his observations, photography supplies the means. It also supplies the means of showing to a roomful of spectators what could otherwise be seen by but a single observer at one time, and has thus rendered to the popularisation of science no less a service than it has led to its advancement. The universal use of photography for purposes of demonstration must certainly not be forgotten in however brief a summary of its applications.

**HIGHER EDUCATION FOR THE PHARMACIST.**

**BY JOHN M. FRANCIS.**

The hearty support accorded this idea by the leading spirits of the pharmaceutical profession at the meeting of the Seventh International Pharmaceutical Congress at Chicago, points to the fact that the profession is awakening to its own weakness, and is beginning to see that the remedy lies within itself.

Every druggist is ready to concede that something is wrong—and when I say "druggist" I mean both the proprietor and the dispensing pharmacist, who is or who hopes to be a proprietor. This lack of proper tone is ascribed by different individuals to various causes: one complains of cutting; another, of competition by merchants; then the soda-water nuisance, the cigar counter, etc., are imprected. The proprietors complain of insufficient help and the salaried pharmacist of low wages. A moment's thought will plainly show where our chief difficulty lies; these evils are all the outgrowth of competition—not healthy, well-regulated competition, which insures pure medicines and polite attention, but the senseless, frantic struggle for place or for sales, which does not allow a reasonable profit for the proprietor or a living salary for his employees; a competition which prostitutes the noble art of pharmacy to the level of the "cure-all" vendor.

Too many pharmacies and too many pharmacists. How may this unhealthy state of affairs be remedied? We answer unhesitatingly: By educating the pharmacists; by weeding out the incapables who drag it down to the plane of vulgar dickering. Do this, and the business will correct itself.

The indignant response is heard: "There are in our ranks men as highly educated, both professionally and otherwise, as are found in any walk of life." True, and these are the men who have pledged themselves to the very reform we are advocating; when we speak of a profession we refer not to the shining lights, not to the few who show of what it is capable, but to the rank and file—each and all who go to make up its personnel.

Is pharmacy a profession or a trade? In other words, are the men who prepare and distribute the agents of our physical conservation or destruction, as it may be, to class themselves with those noble orders whose members must undergo years of preparation, involving the highest mental and technical training, or are they content to be numbered among those from whom nothing more is demanded than a familiarity with routine work and shop details? Are their intellectual attainments to be no higher than is necessary to sell a box of pills or measure an ounce of tincture of opium, as the grocer's clerk would a bar of soap or a pint of molasses? Surely no pharmacist will answer in the affirmative. When the boy wishes to learn the trade of shoemaker, he undergoes no particular mental preparation; he serves under the personal direction of some one who follows the trade until he learns shop details, how to handle his tools, what one individual can teach him, and he his trade. He spends no time delving in the stores of experience and logical thought accumulated by those who have preceded him; furthermore, his lack of knowledge or
Expertness does not entail any serious consequences upon his patrons. Can the same be said concerning the pharmacist, who may be so potent a factor for good or evil? He is one of the last arbiters of the fate of man, so far as this existence is concerned. Menaced humanity turns to the physician and the pharmacist for help, and how censurable is he who offers himself as a pillar of safety when in reality he forms only an insecure support!

Pharmacy is not a trade, but a profession—one of the noblest and most responsible; and we have a right to demand for it men of the highest qualifications, no matter how arduous the task of preparation may be. If the aspirant has not the physical or mental stamina to undergo the necessary preparation, let him enter some walk of life whose responsibility is less. Make this the touchstone of preference, and competition will be reduced, pharmacists will cease to depend on side-lines for their profits, none but the deserving will ask for our patronage, and they will be rewarded as they deserve.

We must bestrider ourselves and keep abreast of the times; the things which were good enough for our fathers are not good enough for us. Conservatism is as bad a master as ignorance. The scope of modern pharmacy has been enormously extended, even during the last ten years; the man of drugs depends less and less on the direct productions of nature; he does not deal so much in "roots, barks, and herbs made for the healing of the nations," but the whole universe is ransacked for his benefit.

The gross forms in which nature puts up her medicines is being criticised. The most magic powers of chemistry are brought into play, and from these bundles of inert tissues and cells the "active principles" are extracted, so that the nauseous dose of yesterday is dispensed to-day in a minute capsule. Not content with what we found, they invent new ways and new methods of becoming worth what they had before. Modern progress and commercial methods alike render it necessary that he should be conversant with botany and materia medica in their latest developments.

How is the would-be pharmacist to attain such an education? Not by serving a certain number of years behind the counter; not by reading at night when body and soul are weary; not by spasmodic efforts, but by patient continued effort under good teachers, in the most favourable environment, having at his command the best modern appliances of his art. He must be free to apply himself unreservedly to study and investigation. Such a system of study will broaden and train his faculties as nothing else will. Cramming or mental stuffing may enable the student to pass a board of examination, but leaves him with a mental indigestion from which he never recovers.

It follows, as a matter of course, that there must be an educational basis on which to rear this scientific superstructure; the proper place to obtain this is in our common schools, which are accessible to all at almost no cost. The fact is, our young men are in too great a hurry to enter professional life; the national unrest pervades all ages.

The question arises: Shall the applicant for pharmaceutical honours be forced to meet certain pharmaceutical requirements?

The welfare of the body politic is paramount to that of the individual; we have a right to demand that our professional servants keep abreast of the times, and such wise limitations will work no injustice. He who has the will and capacity to make a good pharmacist will find them no burden; they will rather serve to relieve him of the competition of the unworthy.—Pacific Druggist.

**Opium trade of Isphahan, Persia.**

At the first, this crop (1893) was not expected to be a good one, as the severe frosts in spring severely damaged the young crops; on the whole, the output has not been a real good one, but it has been somewhat better than was thought. Large quantities were brought in from Burugird (about 6000 mgs); this opium is not used for direct exportation, as it is not very good, being deficient in morphine, on the average it only containing some $3\frac{1}{2}$ to 8 per cent., whilst 10 to 11½ per cent. is the amount admissible. It is used for internal consumption and for adulterating such opium as contains morphine above the required quantity. In London and China the markets were not too favourable, and did not encourage the exporter, but latterly, owing to the high exchange, the market has become more open, and the export can be carried out at a profit, consequently some 2200 boxes in all have been accounted for; the present prices range higher than ever previously known. In late years there has been a decided decrease in the output of this crop. A few years ago an average crop would be returned at 4000 boxes; in 1889, a fair year, it was about 3500; last year it was only about some 2000. It would appear that Persian opium has lost some of its hold on the China market, and thus the cultivation of it in this district has been somewhat discouraged. But also it seems that the cultivator is working out his ground. Year after year he plants the same succession of crops, getting sometimes as many as three crops from it. He does not plough deep, nor does he manure heavily, but only top dress; in consequence, it is found that a jereeb which used to give a crop of 3 mams now only gives from $3\frac{1}{2}$ to $4\frac{1}{2}$ of a man of opium. For the present year an area has been planted which is calculated to give some 2500 boxes. It is anticipated that in the following year a very much larger quantity will be planted. The Persian merchants are looking with keen and anxious eyes to the proceedings of the Opium Commission in India, and their future conduct will be greatly biased by its report.—Consular Report.
With the exception of the elementary science the examination does not go much beyond what is required in the Preliminary, and it may be safely stated that any chemist's apprentice should in three years have learnt enough of the additional subjects to acquit himself credibly as a candidate for a Bell Scholarship. The same holds good of the Manchester Association Scholarship, and the fact of the competition for it being limited only renders the absence of competitors the more remarkable. The intrinsic value of a Bell Scholarship ought to be in itself a great inducement to apprentices to enter into competition. In addition to the money payment of thirty pounds, free admission to the laboratory and lectures of the School of Pharmacy is granted for the year. Opportunity is thus afforded for becoming a Pereira medallist, and reference to the Calendar will show that the position acquired by a Bell scholar is an important step towards securing that great pharmaceutical distinction.

The particulars stated above are matter of common cognisance, or at least should be so, since they are fully set forth in the Society's Calendar every year. But notwithstanding that circumstance, the advantages to be gained by competing for scholarships have not hitherto met with so much consideration as they deserve. In the address delivered by Mr. C. B. Allen at the inaugural meeting of the school connected with the Sheffield Pharmaceutical and Chemical Society on Thursday last, attention was particularly directed to this matter. From a comparison of the number of competitors for the Bell Scholarships, during the past ten years, with the number of those who were qualified to compete, it appears that the disproportion is so enormous as to appear "almost ridiculous" (see p. 305). On previous occasions regret has been expressed that so few young pharmacists come forward to compete for the Bell Scholarships; but it has been chiefly among the examiners that this view has been entertained, and Mr. Allen has done good service by referring to the matter under conditions which may be expected to ensure a wider consideration of the advantages which are now too much overlooked.

It is not, however, merely the possibility of winning a Bell Scholarship that is to be regarded as a powerful inducement to enter as a candidate. There can, of course, be only two successful competitors each year; but what may be regarded as a still greater advantage resulting from the award of these and other scholarships, provided the competition for them were more extended, is the occupation of students' minds with the subjects of the examination, and the consequent instruction that might be acquired during the period of apprentic-
ship. That alone would be a substantial acquisition of incalculable value, whether the scholarship was gained or not. If the prosecution of study with a view to competing for the Bell Scholarships were made a general practice during apprenticeship, a very efficient compensation for the want of a compulsory curriculum would be provided. Apprentices in the provinces as well as in the metropolis and in the larger towns would thus be usefully advanced towards satisfying the requirements of the Boards of Examiners when they seek to obtain qualification as chemists and druggists. We trust, therefore, that Mr. Allen's statistical demonstration of the neglect hitherto prevailing the desirability of competing for scholarships will not continue in future to be lost sight of, either by apprentices or their masters.

THE SALE OF CARBOLIC ACID.

In commenting upon the frequency of poisoning by carbolic acid, the British Medical Journal insists upon the necessity of distinguishing such poisonous articles from articles of food and drink or ordinary domestic commodities. It is urged that the indiscriminate sale of both kinds of articles by grocers and general dealers of all kinds, as in the case of carbolic acid, involves serious risk to the public, which the Pharmacy Act was intended by the legislature to prevent. The mere association of such a poisonous material as carbolic acid with the harmless articles of domestic utility creates a danger by leading purchasers to suppose no greater caution is required in one case than in the other, and by giving undue facilities for obtaining poison. As in the case of other poisons, that danger can be guarded against only by keeping the supply of poisons as a matter of trade absolutely apart from that of the more ordinary necessities of daily life.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

In a circular issued by the Council of this Association, it is pointed out that, at the last annual meeting, a resolution was unanimously carried urging the Council to make an effort to secure the hearty co-operation of every chemist in the town and district in the work of the Association. The present unsatisfactory condition of pharmacy is stated to be owing chiefly to the want of union amongst pharmacists, and in view of the fact that a federation of local chemists' associations has been formed, which affords a basis for all the associations in the country to work in harmony, it is therefore most desirable that each local association should have the active support of every chemist in its district. The Nottingham and Notts Chemists' Association is one of the oldest kind in the kingdom, and its constitution affords scope for dealing not only with educational matters but also with any question of pharmaceutical politics that may be brought forward. Local pharmacists are therefore asked, in their own interest as well as for the general good of the trade, to become members. Arrangements are being made to hold during the coming winter a series of bi-monthly meetings, which will be of a social character, and open for the discussion of trade matters. Due notice of these will be given. Any further information will be furnished by the honorary secretary, Mr. William Gill, 207, Radford Road, Nottingham.

THE SERUM TREATMENT OF DIPHTHERIA.

Though the published information relating to this subject is not only meagre but in some particulars contradictory, we have endeavoured to gather from the accounts recently given some indication of the method by which a product suitable for medical use is to be obtained, as that is the point of chief interest to our readers (see page 291). In the Daily Telegraph of Monday last there was a long article on "The New Diphtheretic Cure," evidently written under the influence of the sensation created by Professor Behring's paper, read at the meeting of naturalists and physicians in Vienna. The facts there stated are the same as those mentioned in this Journal last week (see p. 278), but the comments upon them appear to have a more confident tone than the present slender knowledge of the subject altogether justifies. Thus, for instance, the statement that as a material for injection the serum is absolutely innocuous appears much too positive even if it be certain that its effects are useful.

MR. OCTAVIUS CORDER.

At the last meeting of the Board of Examiners in London, a resolution recording the sense of the Board of the services rendered by Mr. Octavius Corder during the twenty-one years he has been an examiner, and assuring him of the respect and good wishes of his colleagues was most cordially adopted. Mr. Corder is ineligible for future election under Section X of the Bye-laws.

BENEVOLENT FUND.

The names of the seven approved candidates for the election of four annuitants in December next will be found, together with particulars of their respective cases among the official notices at page 5 of the advertisement matter.

WATT'S DICTIONARY OF CHEMISTRY.

The fourth volume of this important work has just been published, and British chemists have now a complete work of reference adapted to the present position of the science. Owing to the lapse of six years since the first volume of the dictionary was published, the contents of the earlier volumes will require to be supplemented with the results of investigations carried out meanwhile, and it is to be hoped that this want will be provided for, as in the previous edition, by the early issue of a supplementary volume.

JAPANESE PLANTS.

It may interest some of our readers to know that herbarium specimens of Japanese plants, both phanerogams and cryptogams, can be procured, some specimens that have been sent over as samples being excellent. They are carefully dried and mounted, each specimen being protected by a tough tissue paper, through which the plant may be seen. The enterprising Japanese who supplies these specimens is also a seedman, and his address is Keigo Saito, Kosobe, near Takatsuki Station, Osaka, Japan.
Transactions of the Pharmaceutical Society of Great Britain.

DONATIONS.
At a meeting of the Library, Museum, School, and House Committee, held on Wednesday, the 10th inst., the Librarian presented the following report of donations to the Society's Libraries.

To the Library in London.
Royal Society of New South Wales:
Journal and Proceedings, vol. 27.
Institute of Chemistry, London:
Regulations and Register, 1894.
University of Glasgow:
Calendar, 1894.
University of Edinburgh:
Calendar, 1894.
University College, Bristol:
Calendar, 1894.
Owens College, Manchester:
Calendar, 1894.
Yorkshire College, Leeds:
Calendar, 1894.
School of Medicine, Edinburgh:
Official Calendar, 1894.
Professor Attfield, London:
Chemistry, 14th (U.S.) ed., 1894.
C. A. Barber, M.A., St. John's, Antigua:
Four supplements to the Leeward Islands Gazette. Agricultural Journal of the Leeward Islands, no. 1. The treatment of diseased sugar canes in the West Indies, 1894.
Frisasche Brothers, New York:
Descriptive catalogue of essential oils and organic chemical preparations, by F. B. Power.
Institution of Civil Engineers, London:
List of members, 1894.
U.S. Bureau of Education, Washington:
Statistics of public libraries in the U.S. and Canada, by Weston Flint.
Dr. C. O. Cartman, St. Louis, U.S.:
Lessons in qualitative and volumetric analysis, 4th ed., 1894.
H.M. Secretary of State for India:
The Bower manuscript, edited by A. F. R. Hoernle, part 1; part 2, fasc. 1, 1893-94.
Herr E. Disterich, Helfsenberg:
Helfemberger Annalen, 1893.
Ontario College of Pharmacy:
Annual Announcement, 1894.
Mr. W. West, Bradford:
On some freshwater algae from the West Indies.
Mr. J. C. Sawyer, Brighton:
Rhodologia, 1894.

To the Library in Edinburgh.
Ontario College of Pharmacy:
Annual Announcement, 1894.

EXAMINATIONS IN LONDON.
October, 1894.
(Continued from p. 284).

MINOR EXAMINATION—PASS LIST.
Candidates examined. 228
failed. 150
passed. 78

Amess, Albert Edward.
Angel, Edward Charles.
Appleyard, Percy.
Ault, Percy.
Bates, Sydney Lancaster.
Benjamin, Joseph.
Bennett, Frederick.
Brack, David George.
Brewer, Walter Joseph.
Bryant, Nicholas John Andrew.
Charles, Thomas Watkin.
Charlesworth, Charles Edward.
Clarke, John George.
Cleghorn, James.
Cocker, Lewis Alexander.
Cole, Arthur.
Coulter, George Etches.
Coward, Miles.
Cullwick, John Henry.
Dawney, Charles Benjamin.
Dickinson, William.
Durbin, Henry Eastman.
Evans, David.
Flaher, George William.
Freeman, Alfred Percy.
Garwood, George James.
Gilson, George Shaw.
Griffiths, Frederick Gray.
Harrison, John George.
Hemming, John Wilson.
Hewitt, Silas.
Holroyd, James.
Hutchinson, James Herbert.
Jenkins, Morris William.

Morrey, George.
Moultrie, George Briggs.
Neal, Frederic.
Neatheroat, Harry William.
Ockwell, Edwin.
Pearce, William Forward.
Potter, Henry Arthur.
Pratt, George Joseph.
Rist, William King.
Rogers, Frank.
Rosser, Samuel.
Ruxton, James.
Scruby, John Charles.
Smith, Charles.
Steeds, Frederick George.
Stelzox, Walter Edmund.
Stratton, William George.
Swaffin, John Phillips.
Tattersall, John.
Taylor, Archibald Leonard.
Taylor, Arthur Ernest.
Taylor, Charles John.
Taylor, Thomas Roll.
Thomas, Hugh William.
Thomas, John Oliver.
Thompson, Edward John.
Tully, Fred Herman.
Tutt, George Francis.
Wallis, Robert Acrid.
Wardey, Thomas.
Webb, Joseph John.
White, Henry Fox.
Williams, David Isaac.
Williams, John (Baglilt).
Williams, John (Corwen).
Wilson, Arthur Frederick.
Wood, Arthur Henry.
Woodliffe, Henry Grayson.
### MODIFIED EXAMINATION—PASS LIST.

Candidate examined and failed .......... 1

### FIRST EXAMINATION—PASS LIST.

Certificates by approved examining bodies were received from the undermentioned in lieu of the Society's examination.

- Brown, Harold Edwin ............ Hull.
- Carey, Frank Russell ............. London.
- Dunn, William Robinson ......... Blackheath.
- Finn, Francis Dudley ............. Dover.
- Gibb, William C. N ............... Winchester.
- Jarrett, Jarret Roberts .......... Trawsfynydd.
- MacGregor, John .................. Glasgow.
- Moore, Lucy Bramley ............. London.
- Nelson, George ................... Oldham.
- Palmer, William .................. Lynn.
- Pyman, Frank ..................... Stowmarket.
- Stanley, John ..................... Leamington.
- Sykes, Richard Alfred ........... Manchester.
- Wilson, Francis M ................ Stowmarket.
- Wilson, Robert William .......... Sunderland.

### EXAMINATIONS IN EDINBURGH.

**October, 1894.**

### MAJOR EXAMINATION—PASS LIST.

- Candidates examined and passed ........ 2
  - Elder, Alexander.
  - McKenzie, Thomas.

### MINOR EXAMINATION—PASS LIST.

- Candidates examined ................. 91
  - passed ................................ 46
  - failed .............................. 45

- Adams, George Cuthbert.
- Alock, James Elsworth.
- Allan, William.
- Allison, John Robert Billiard.
- Atherton, William.
- Bain, James.
- Blount, George Wright.
- Buse, John.
- Dean, Arthur Shiera.
- Duncan, James George.
- Eastwood, Horace.
- Ferguson, William Cross.
- Fyfe, John.
- Gilmour, Andrew.
- Gilmour, William.
- Hughes, John Hampden.

- Steven, David.
- Taylor, William Stewart.
- Watson, David.
- Whaley, Charles Edward.
- Whitby, Harold Outbier.
- Wolstenholme, Jesse.
- Wray, Thomas.

### FIRST EXAMINATION QUESTIONS.

*October 9, 1894.*

#### LATIN.

*Time allowed—from 11 a.m. to 12.30 p.m.*

1. **(For all Candidates.)** Translate into Latin:—
   1. The wise citizens will give books to their boys.
   2. The boys will be punished by the learned judges.
   3. He denies that disgraceful things can be useful.
   4. Caesar leaves the city that he may command the army.
   5. There is no doubt that they drove the virtuous men from the city.

2. **Translate into English either A (Caesar) or B (Virgil).**

(Candidates must not attempt both authors.)

#### A. CAESAR.

1. Ob eas causa et munitioni, quam fecerat, T. Labienum legatum praefecit; ipse in Italianis magis itineribus contendit, duasque ibi legiones conscriptas et tres, quae otrum Aquileiam habebant, ex hibernis educit, et, quae proximam iter in ulteriorum Galliam per Alpes erat, cum ibi quinque legionibus ire contendit. Ibi Centrones et Graecos et Catuvriges, locis superioribus occupatis, itinere exercitum prohiero cantuam.

2. Si quae adversum procul et faga Gallorum commoveret, hos, si quaserent, reperire posse, diuturnitate belll defatigat Gallus, Ariovistum, quorum multis mensae castris se ac paludibus tenueisset neque ad potestatem fecisset, desperantes jam de pugnas et dispersos subito adoration magis rationes et consilio, quam viritate, vicisse. Cul rationi contra homines barbaros atque imperitos locis fuisset, hae ne ipsum quidem speraret nostris exercitus capi posset.

#### Grammaratical Questions.

(For those only who take Caesar.)

1. Decline, in full (in the singular), *proximum iter*, and (in the plural) *duas legiones* (Par. 1).
2. Give the degrees of comparison of *dulcis, altus, majus, multus, dignus, graviter*.
3. Give the principal parts of *spondeo, carere, paro, morso, ero, abs*.
4. In what manner are direct interrogative sentences translated into Latin? Give examples.

#### B. VIRGIL.

1. Namque, sub ingenti laustrat dum singula templum, Regnum opperient; dum, quae fortuna sit urbi, Artifliciumque manus inter se operumque laborum Miratur; velit illas ex ordine pugnas, Bellique jam familia totum vulgata per orbem, Adriades, Frisiamque, et saevum ambobes Achillen.

2. Nec non et vario noctem sese monebat
   Infixus Didò, longumque bibebat amorem,
MULTA super Prisio rogantia, super Hector e multa;
Nunc, quibus Aurorae venissent filius arumis;
Nunc, quales Diomedis equi; nunc, quantas
palæas.
"Immo, age et a prima dic, hospes, origine
nobis.
Insidia," inquit, "Danaum, casaque tuorum,
Erreroseque tus; nam te jam septima portat
Omnibus arenantium terris et fluctibus aetas."

Grammatical Questions.
(For those only who take Virgil.)
1. Decline, in full (in the singular), Infelis Dido,
and, in the plural, Errores tuos (Par. 2).
2. Give the degrees of comparison of dulce, altus,
maius, miatus, digne, gravius.
3. Give the principal parts of spondéo, cavéo, pasco,
mergo, emo, limo.
4. In what manner are direct interrogative sen-
tences translated into Latin? Give examples.

ARITHMETIC.
Time allowed—from 12.30 p.m. to 2 p.m.
[The working of these questions, as well as the answers,
must be written out in full.]
1. What will a piece of plate cost which weighs
3 lb. 4 oz. 5 dwt., if the price of silver be 56d. per
l. and the charge for workmanship £3 6s. per lb.?
2. The fore-wheel of a coach is 2 ft. 1 in. round, the
hondl wheel 13 ft. 6 in. round; how many more revolu-
tions will the former make than the latter in the
course of a mile and a quarter?
3. How much will 6 lb. of 190 yards amount to at
5s. 6d. for 6 oz. of 13 yards (Long Measure)?
4. Simplify the following fraction, giving the
answer to five places of decimals:—
\[
\frac{5001 + 201}{3001 - 106} \\
= \frac{5001 \times 3001}{\text{ }}
\]
5. A beam is 14-14 metres long, 51-6 centimetres
wide, and 174 millimetres thick. How many cubic
metres does it contain?
6. If the carriage of 8 cwt. 3 qr. 14 lb. for 104½
miles costs £1 16s. 10d., what should be charged
for the carriage of 5 tons a distance of 98 miles?
7. A wine-merchant gains \frac{1}{7} of the cost of a
gallon of wine by selling it at 21s.; what would be
his gain per cent. if he sold it at 22s. 6d.?

ENGLISH.
Time allowed—from 3 p.m. to 4.30 p.m.
1. Parce fully:
"It becomes the throne of monarch better than
his crown."
2. What do you understand by (a) the Nominative
Absolute, (b) Nouns in apposition, (c) the Indirect
Object? Give one sentence in illustration of each.
3. Give the meaning and derivation of the following
words:—procrastination, braggart, amphibious, circum-
navigate, antipathy.
4. In the following passage supply the necessary
capital letters, and put in the stops and inverted
commas where necessary:—once he asked tom davies
whom he saw drest in a fine suit of clothes and what
art thou to-night tom answered the thame of ross
which it will be recollected is a very inconsiderable
character o brave said johnson
5. Write a short composition on one of the follow-
ing subjects:—
(I) The Last Session of Parliament.
(II) The Tower Bridge, or The Manchester Ship
Canal, or The Tay Bridge.
(III) Modern Improvements in Methods of Lighting.
(iv) "Content is a kingdom."

* This question must be attempted by every candidate.
At any rate we must work nearer the level of the average assistant chemist, and if by extended education this rises, so that he can give an intelligent hearing to these papers, then it will be fit time to arrive at it. It is expected of an assistant, say with the Minor qualification, coming to a meeting for the first time and hearing some of the highly edifying intricacies of synthetic science, but that he will leave with the feeling, not altogether without foundation, that we are too scientific to be of service to all.

More popular have been the evenings devoted, from time to time, to the discussion of matters of trade import, pharmaceutical politics, and educational topics. It is impossible to too strongly impress upon all the value of giving these attention and thought, of endeavouring to form one's own opinions of them instead of taking them at second-hand, of considering what possible changes can be made where changes seem desirable, and making a point of giving effect to one's conclusions in the course of discussion. As a means of cultivating the art of speaking in public, to make a distinction between the better and the worse, and to make the conduct of these examinations, the consequences would be so material as to compensate for a great additional expenditure of money or trouble. As regards the systems by which education is obtainable, the bulk of the teaching devolves upon the number of schools in this metropolis, where up to a year ago really good and painstaking teaching is done, and where the short courses I referred to before are arranged, more than any other reason, to cope with the demand for them. But such schools, promoted as commercial enterprises, are wanting in the traditions that make students proud of their own and able to appreciate the others, and to help them to continue afterwards fellowship with the men with whom they worked. These schools have to be in competition for existence with the well-endowed school of the Society, with the usual consequence of competition, that a prejudice arises, in this case against the Society itself, by which is collected, after the manner of a country school, and because of its indirect effect upon us.

Council has sent prospectuses to nearly every chemist's shop in the metropolis, and I ask every member to second this effort by personally canvassing their own acquaintance.

During the last two years I have had the opportunity of seeing a very large number of chemists' assistants, and the more I have seen of them the more have I been impressed that the root of all the disunion in our trade, and therefore largely affecting us, is the insufficient education so many receive, and the systems of pharmacy by which education is obtainable, it is useless to expect an average man, who has for his examinations (certainly not for his training) a short course of six weeks or so, or even a series of such short courses at a school, to be able to take an interest in any matters of pharmaceutical progress, or in any requiring but the most elementary considerations. We cannot get hold of him, and no movement, however beneficial to himself, will be able to claim him. It seems to me the holding of the Society's examinations at intervals of but three months from each other gives a tacit encouragement to this abuse, and difficult orthodoxy and inability to the better trained. It is to make the conduct of these examinations, the consequences would be so material as to compensate for a great additional expenditure of money or trouble. As regards the systems by which education is obtainable, the bulk of the teaching devolves upon the number of schools in this metropolis, where up to a year ago really good and painstaking teaching is done, and where the short courses I referred to before are arranged, more than any other reason, to cope with the demand for them. But such schools, promoted as commercial enterprises, are wanting in the traditions that make students proud of their own and able to appreciate the others, and to help them to continue afterwards fellowship with the men with whom they worked. These schools have to be in competition for existence with the well-endowed school of the Society, with the usual consequence of competition, that a prejudice arises, in this case against the Society itself, which I am afraid is apt to be shared by the students themselves. This is a matter somewhat outside the limits of this address, but I mention it to let assistants know that this Association possesses the good will of all the principal tutors in the metropolis, and to give publicity to the fact that competition is only fair in a particular school, and because of its indirect effect upon us.

I should like to direct a few remarks to one other class of men, the type of whom points to the tendency of trade, in the formation of store and company pharmacists, and, whilst bewailing their probable effect upon his future profits, ridicules the claims of extended knowledge, or the practice of "your duty to your fellow craftsmen," preached in this room. Gentlemen, unless the people of this country and the medical profession, who hold the power largely to do it, wish to banish all progress in medicine and to establish the state of pharmacy we can rest on in the future, we must not make the portion of the address fall upon you. The question naturally occurs at this stage, how much support have we been able to gain? About the answer—some 160 assistants belong, out of perhaps 2000 in London, 500 of whom would be free to attend our meetings—I should like to say a few words! The reasons of support are the same that confront every movement in the trade—the apathy and lack of Espirit de corps. To endeavour to overcome these, the
so much gold as the enterprising storekeeper, but he can command greater respect and social recognition, and boast at least of a congenial pursuit.

In conclusion, gentlemen, I must appeal earnestly for hearty support during the coming session. This Council has, even thus early, sustained the loss of several of its most prominent members, owing to business calling them from London, and the success of this session will depend entirely upon the energy displayed by the rank and file of members. On that account, as well as because the benefit received from this Association stands in direct ratio to the assistance each member gives, I ask your regular attendance at our meetings and participation in our work. The programme for the first half-session you will all have received. There is nothing in it to single out for especial mention, as every item possesses distinct interest. On the evening devoted to short papers I hope we shall receive some useful notes, and I ask, on behalf of the secretaries, any who may come upon some little difficulty they are unable themselves to work out, to hand it to the secretary, who will be pleased to find someone willing to do so. And now, gentlemen, it only remains for me to thank you for listening in such a kind way to much that must have been tedious.

At the conclusion of the address, Mr. H. H. Robins rose to propose that a very hearty vote of thanks be accorded Mr. Jones. This was seconded by Mr. Gane, and being put to the meeting was carried with acclamation. The proceedings were then adjourned.

---

**Provincial Transactions.**

**SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.**

The tenth session of the Sheffield School of Pharmacy, conducted under the auspices of the above Society, was inaugurated on Thursday, October 11, when the presentation of prizes to the successful students of the past session was followed by the reading of the following:

**Introductory Sessional Address.**

**BY CHARLES B. ALLEN,**

**Member of Council of the Pharmaceutical Society.**

I have to thank you for the honour you have done me by your invitation to share in the social pleasures which mark the commencement of a new session, but I am somewhat concerned for the reputation of my friend and colleague, Mr. Newsholme, whose kindly good-fellowship can alone justify his temerity in submitting my name to you as that of a fit and proper person to deliver an address.

I have always thought that the first reflection which must arise in the mind of any person who has undertaken a duty of this description must surely be a devout wish that some other than himself had been chosen to do it; and in yielding to your desire, I have come to you with a foreboding that it would have been better for you if such had been the case to day.

Yet if by virtue of twenty-eight years happily passed in the practice of pharmacy I may be able to give some slight encouragement, or present some fresh incentive for work, to those who are younger than myself, then indeed my coming amongst you may not altogether be purposeless or ineffectual. For some reasons too this opportunity gives me great pleasure, principally because as a pharmacist, carrying on my vocation in suburban London—where all questions relating to pharmaceutical education are easily delegated to the central authorities—I am able to express my admiration for the public spirit and strong untiring effort which leads to the foundation, and what is far more important, continually supports a local centre of education, such as is so well exemplified by the Sheffield School of Pharmacy. No words of mine can either exaggerate or enhance the value of this and kindred institutions in the provinces to those students who from the first days of their apprenticeship avail themselves to the full of the advantages they offer. I can assure every student—whether he is entering the classes now for the first time, or progressing through former tuition to more advanced work—that if he carefully follows the plan which the experience of his teachers here will suggest for him, his chances of ultimate success are at least equal to those of any of his co-workers in the kingdom. If I were to contrast the advantages of youths in provincial towns, who have access to classes, with those which are enjoyed by an apprentice in London, I could not readily admit that the latter is the more privileged.

The classes which are held at the School of Pharmacy in Bloomsbury Square are of necessity advanced beyond the capacity of a lad at the age upon which he usually enters upon his apprenticeship. Therefore, a youth who would properly avail himself of the instruction given must have assimilated a good deal of elementary knowledge before he could hope to commence his complete curriculum with any credit to himself or satisfaction to his teachers. But by taking up one subject at a time, and so proceeding through the whole period of his pupilage, he may be justified in the hope that he will have prepared himself to receive and understand the final course of instruction, just as you yourselves will expect to do after having given serious attention to the classes held here during this and subsequent sessions. Then if perchance you should meet—as I earnestly trust you may aspire to do—in honourable competition for the valuable prizes which are offered by the Council of the Pharmaceutical Society, I feel sure you would willingly acknowledge that the advantages on the one side are no greater than those upon the other.

The mention of prizes leads me to a subject of very much importance to all pharmaceutical students. I am inclined to think that sufficient attention has not been paid to certain particulars concerning some very substantial prizes which are specially worth your attention, because they are intended to be well within the range of study during apprenticeship. One of the first things which I should endeavour to impress upon a youth at the outset of his career would be that he should read carefully all those portions of the Calendar of the Pharmaceutical Society which touch upon the subjects of prizes and examinations. He cannot but find it profoundly interesting and instructive. I regret very much that there are many young men who, although they have adopted pharmacy as their vocation, persistently neglect to take a full and com
prehensive view of all that lies before them, and who even pass the whole period of their apprenticeship in happy ignorance of some of the things which should be realised long before they have gone so far upon the road to discouragement and inevitable failure. A few hours' careful perusal of the Calendar will be sufficient to give any lad a clear insight into the whole plan of study which lies before him and must be accomplished before he can gain his qualification, whilst a contemplation of the list of prize winners should prompt him to use his utmost endeavours to attain similar distinction. In this selfsame volume he will find a number of facts which will convince him that the Pharmaceutical Society of Great Britain exercises even a paternal interest in him throughout his educational career, and that a brotherhood, consisting of its members, spreads over the whole surface of the globe. I can assure him, from the warmest recollections of my own experience, that he will thus gain strength, reliance, and increased knowledge by association with the Pharmaceutical Society from the moment when, by reason of his passing the "First" examination, it has become possible for him to do so.

It occurred to me that it might be interesting to glance for a moment at the figures which show what proportion of the students who pass the First examination give in their subscription to the Pharmaceutical Society, either from a conviction upon their part that it is a good thing to do, or from the desire of their parents or guardians that they should thus early be associated with the parent Society. For this purpose I have made a tabular statement, showing the number of students year by year during the last ten years who have passed the First examination, and the number of similar rank who have joined the Society in the same time. You will notice that of the total number who have passed their Preliminary, a little less than half have joined the Society. Of course, it must not be assumed that the students who have joined in any one year are those who have passed in that year, but as one year overlaps another, by taking ten years a very good illustration of what the proportion really is can be readily shown.

Number of those who passed the Preliminary Examination.

It is satisfactory to find that so many of our young men have thus recruited the ranks of the Pharmaceutical Society at a time when the prestige of the body corporate, through the continual advancement of its educational work is of the utmost importance to them, and will powerfully influence them in their work as individuals. I venture to believe that just in proportion as they may act worthily for their Society, so will they be eager to announce the value which this early attachment had for them. I should not have troubled you with these details and figures, but for the reason of inviting your attention to a subject which presses upon you more closely, and in which I also feel some concern. Perhaps, because my name can be found in the list of unsuccessful candidates, I have always felt a keen interest in the competition for the Jacob Bell Memorial Scholarships. When one considers the number of students who are eligible to compete for these, side by side with the actual value of the scholarships to their fortunate possessors—as well as the universal admission that all students, he of the genus Pharmaceutical is the most hard up—I cannot find words to express my astonishment that during the last decade the numbers competing for these two scholarships have averaged just about twenty-seven per year. To be a "Bell Scholar" should be the happiest dream of the youthful pharmacist, and the attainment of this distinction for a time, at least, his highest and most constant ambition. I am unable to believe that it is actually realised by the bulk of young men in England, Scotland, and Wales, that two prizes worth from £73 to £80 each are contends for annually by a fraction only of those who must obviously be eligible to do so.

In the year 1884, at the Inaugural Meeting of the School of Pharmacy in London, Mr. G. S. Taylor, for himself, and his co-examiner Dr. Thresh, called attention to the fact that the number of candidates for the Jacob Bell Memorial Scholarships had again fallen off, there being in that year only twenty, whilst in 1883 there were twenty-five, a number that was so much in advance of previous years that a hope was then expressed that the value of these scholarships was becoming more widely recognised. Mr. Taylor also said that upon "more than one occasion he had had to express his regret that so few young pharmacists can be found to compete for this prize, but he hoped to see a larger competition in future years." By tabulating the number of competitors for the last ten years we are able to see to what extent this hope has been realised.

Number of Competitors for the "Bell Scholarships."

It should be noted that from 1888 to 1891 there was included in the above competition a third scholarship of the value of £20, which was founded in honor of Professor Redwood, and bore his name. This scholarship was originally submitted for competition under exactly similar conditions to the Bell Scholarships, practically forming a third prize attainable by students of the Society; but whilst the professor was yet alive, with his sanction and cordial concurrence, it was considered expedient to diverge from the original purpose and convert this scholarship into an award for more advanced students working in the Pharmaceutical Society's Research Laboratory.
This conversation was undoubtedly rendered very much easier by the knowledge that so far as the junior students were concerned, the offer of an additional scholarship had awakened no enthusiasm and attracted no new competitors, and the opportunity thus held out to them was therefore permanently withdrawn. In reiterating and accentuating the regret which was expressed by Mr. Taylor ten years ago, I would beseech every pharmaceutical apprentice in Sheffield, and through them every apprentice in Great Britain, to read and consider the regulations pertaining to these scholarships, with a view to augmenting the number of competitors. The scholarships are founded for them as a class, there is no entrance fee, and the examinations are held annually in July at the forty-two centres at which the Preliminary examinations are conducted and when one reflects that an average of five students from each centre, which is surely no unreasonable number to expect, would bring the total over 200, the average for ten years (of twenty-seven) appears almost ridiculous.

If, by an increased competition, the list of unsuccessful candidates should be augmented ten-fold, you will, by your earnest endeavours to attain this distinction, as well as by the course of study it has led you to pursue, have come so easily into the possession of your qualification, that in the retrospect of your student life you will look with pleasure and gratitude upon the contest which, whilst yet on the threshold of your pharmaceutical career, formed the first incentive to adopt a definite line of study. The Manchester Pharmaceutical Association Scholarship affords another marked illustration of an indifference which is scarcely credible. To a limited class, comprehending apprentices who have been engaged for not less than three years in a pharmacy in Lancashire, Cheshire, or the High Peak Parliamentary Division of Derbyshire, an annual scholarship of about £30 has been offered, with the result that for the last three years, through the absence of candidates, no competition has taken place, and the scholarship has for the time drifted into other channels. I confess myself quite unable to explain, by any process of reasoning, how this is to be accounted for, especially when it is noted that the Manchester Scholar, if he so elects, may have the option of carrying on his studies in any provincial school of pharmacy approved by the Council of the Society, whereas the Bell Scholarships are tenable only in London. This should be an important difference to some provincial students, and if the scope of the Manchester scholarship could be extended so as to apply to the provinces without limitation, I should expect there would be an immediate change from the present unsatisfactory state of affairs. I must not lead you to suppose that I have any authority for approaching this question, it merely presents itself in the line of thought along which I am wandering; but believing as I do, that the best results to pharmacy are gained by setting its apprentices to work from the very beginning, I am extremely anxious that this additional incentive may not be lost to them as the Bedwood Scholarship has been. I venture to hope that, if there is any real desire upon the part of provincial students outside the limits of the present area to become eligible for the Manchester Scholarship, and if that desire could be expressed for them officially, the generous donor, impressed with the failure of his design to benefit a limited district, would throw the scholarship open, under certain conditions, to all apprentices in the provinces, and by so doing provide a prize of such value as to ensure a yearly contest amongst the students of provincial schools, which could scarcely fail to result in much permanent good to a greater number than it ever can do under its present restriction. Those students who are located in large manufacturing towns cannot have the facilities or the collection of plants which are afforded to those in purely country districts, but when there is a love for the subject, the disadvantages of the locality rapidly yield to the enthusiasm of the collector. If engaged actively in business, his opportunities are all too few, yet he will seize upon every one of them, and early in the morning, or late on summer nights he will wander full many a mile from home in search of specimens to add to his ever-growing store. To such a one the Pharmaceutical Society's Herbarium prize naturally commends itself, but as the difficulties of collection and the time required for preparation and mounting somewhat seriously tax the resources of the pharmaceutical student, it is not remarkable that the competition for this prize has always been limited. Considered as an alternative to the chances of gaining a scholarship, the formation of herbaria gives healthy exercise and pleasant, instructive occupation to such apprentices as elect to work in that direction, and if the conditions laid down in the regulations have been followed, there should be no hesitation in submitting the collections for assessment by the Professor of Botany, who would gladly devote the necessary time to the examination of a far larger number of collections than those at present sent in.

At the risk of proving wearisome I have endeavoured to represent, from my point of view, the sense of obligation which should pervade the student's mind when he regards the wider range of prizes which are open to him through his association with the Pharmaceutical Society. I am fully conscious that all the information I have given you could be quite as well gleaned by yourselves in your own quiet hours, but I have assumed it to be just possible that the presentation of these matters in a concrete form may be more strongly persuasive, and if I can be successful in inducing even one from amongst your number to aim higher, to go straight for the bigger game, and at the same time have demonstrated that it is worth going for, I need not then apologise for the dulness of my theme. I do not pretend to possess any capacity for directing you in ways by which your study can be made easier, so that whether you resolve to measure your ability by competition with your fellows for open scholarships, or whether you confine your attention to the prizes which are offered abundantly in this School, you must be prepared for right-down hard work. Your teachers are devoted and enthusiastic, and in their several subjects have signi-
fied their willingness to assist to the utmost extent of their power, and your acceptance of their instruction, with care and diligence, will form their best reward. Never hesitate to consult them in your difficulties, and be guided and directed by their experience towards the goal you have in view. I believe in the exhibition of a definite object held always before you, whilst to strengthen your resolution and make more sure of your aim it should lie directly in your way, and not too far off. Some young men think the qualifying examination is quite enough, consoled themselves with the knowledge that two, three, or four years, as the case may be, must elapse before they are old enough to present themselves. They are loud in announcing their intention of having "a shot at it soon," though they are rarely seen with the necessary gun in their hands; many of these, by the bye, eventually declare the Board of Examiners to be composed of extremely crochety individuals, and, according to their own accounts, are referred to their studies through all sorts of accidental circumstances. I do not agree with their views. Rather would I commend to you the periodical examination, a constant revision of your work, regular entrance for your class prizes, the attainment here and there of a science certificate, or an occasional exploration into the mysteries of the "Student's Corner." These, and others like them, are the stepping stones by which you will ford the stream of knowledge. Opportunities, unknown or unrealised a few short years ago, are now thickly scattered round you. Accept them, ere the time presses and life becomes one long round of labour in the struggle for existence; define your object clearly, and work honestly and systematically towards its achievement.

Even now the time at your disposal is more or less limited, but by devoting one or two hours per day to systematic study it is astonishing how much may be accomplished. Tabulate your subjects, and allot a specific time to each, so as to be able to place every day's work in a conspicuous position before you. In reading without some such arrangement you are not unlikely to give too much time to one subject, and neglect others which ought perhaps to claim a greater amount of attention. If, by unforeseen circumstances, you lose your time and miss the appointed lesson on one day, do all you can to make it up the next; let nothing interfere with the regularity of your work. Two or three years passed in this way effectually lays the "Bogey" of Bloomsbury Square, and he will never trouble you again! Text books have so multiplied in this age, and there are so many short cuts to all sorts of sciences, that there is some fear of a student forgetting how to compile a note book! The young pharmacist at least should not lose this art, nor ought he to be satisfied with merely copying the notes from his lectures, or following on the exact lines which others have laid down. He should cultivate a faculty for digesting his matter by a process of his own, and neatly condense his work into the smallest possible compass, illustrating by diagrams and figures the salient points which will bear that kind of treatment. The student who is neat and methodical in his notes is laying a foundation upon which will be built a neatness and method, a love of order, and an attention to detail, which are chief amongst the essential characteristics of him who best succeeds in pharmacy. Upon the qualifying examination _per se_ it seems almost unnecessary to dilate, no young man who utilises the days of his pupilage in anything like the way which I have tried to indicate need enter the examination room with any feeling of apprehension, for he will be the possessor of an amount of information which has gone beyond the standard required of him there, and he will experience but little difficulty in convincing his examiners that such is the case. The examiners themselves derive no pleasure from the rejection of a candidate, nor do they lightly regard the responsibility of so doing. Their work is rendered difficult and their duties laborious by the large number of candidates who are continually presenting themselves from a sense of compulsion rather than volition; who, after the smallest possible amount of preparation, enter the examination room just for the sake of seeing what the thing is like. The practical examination of the first day has, however, now become so effective through the longer period which is devoted to dispensing and practical chemistry, that it is really difficult for candidates of this class to succeed in getting through this ordeal without declaring their obvious incompetency. The results are sometimes so startling that better things might have been expected from a novice in his first attempts at compounding, which would be a using if they were not also painful. Often enough the men thus demonstrate for themselves the utter impossibility of proceeding further, and signify their wish to retire on account of the wretched failure which lies before them, in an often repeated effort to compound a comparatively simple formula. In their dealings with individuals it is idle to suppose that the examiners do not possess a profound knowledge of human nature, coupled with an average amount of common-sense; they can quite easily distinguish between a purely nervous candidate and the assumption of nervousness to hide incapacity. But as there are some students who cannot avoid a feeling of trepidation whenever they are face to face with an examiner, I would just like to assure the nervous man—if any such be here—that I have myself witnessed an amount of consideration and kindness to a candidate who had manifestly broken down through sheer nervousness, and who, I need hardly say, was an absolute stranger to the examiner, which probably will have the effect of altering his impression of examiners for the remainder of his life.

Through your familiarity with the business of pharmacy you must soon realise that you have adopted a vocation of manifold responsibilities, inasmuch as you are to fit yourselves for becoming the intermediaries in an Act of Parliament, which gives you certain privileges on the one hand and provides for the safety of the public upon the other. I am aware that the privileges are considered by some to be unimportant and barely worth the trouble of attainment, but such as they are you must be prepared to accept them.
loyally until the time is ripe for better things. If you are firm in your adhesion to pharmacy, let your appreciation of it lead you to a high estimation of its possibilities, remembering that if you disparage your vocation, those who are brought into contact with you will do the same. Give yourselves up to the mastery of every detail, however petty, however paltry; they are all worth acquiring; there is so much to do that it will easily absorb all your working hours. Cultivate your powers of observation, and seek an explanation for everything which appears to need it; do not be content with the mere knowledge that it exists, for every cause there must be a reason. Your seniors who have been engaged in pharmacy for many years can tell you, if you seek them, countless things which are worth knowing, which you will value in later years perhaps better than you do now. Above all things pay heed to their counsel, and respect their experiences, until you are able to discover better ways for yourselves. If you are inclined to think them faddists, remember that their fads have endured the test of time. “Knowledge comes, but wisdom lingers,” is true to them and true to you; you may be on the high road to the one, but you must be content to wait for the other.

If the miscellaneous nature of the trade you are engaged in necessitates the handling of many things which are unconnected with pharmacy, if your work is rough and sometimes arduous, you are none the worse for that, for many of the masters in your craft have trod the self-same paths; and providing you do your duty in all things with cheery and determined purpose to excel in each, you will assuredly find in due season, out of your own experience, that the evolution of the pharmaceutical chemist, by easy gradations from the country apprentice, is not only possible, but has become an accomplished fact.

To you who would go further still, the chart lies open, and all its ways are plainly marked. You may obtain admission and opportunities of continued labour in the Research Laboratory, the Pharmaceutical Society through its Council having thus made it possible for you to become a worker for the common weal. Whether your enthusiasm ultimately devotes you to the practice of pharmacy, or whether it leads you out into the wider fields of science, you will still remain a true child of your Alma Mater, reflecting your successes upon the teachers of your earlier days and ever ready to acknowledge the gratitude you owe to them. Give heed to them now, the road will widen and you know not whither it leads—follow trustfully until you find it pointing clearly to that great opportunity which so mysteriously shapes its ways, that once at least in life it comes to all who work and wait.

LIVERPOOL PHARMACEUTICAL STUDENTS’ SOCIETY.

The annual meeting of this Society was held at the University College, Liverpool, on Thursday, October 4, the president, Mr. Frank Walker, in the chair. The following officers were elected for the ensuing session: President, Mr. R. Mitchell, Old Swan; Vice-Presidents, Mr. R. C. Cowley, Ph.C., and Mr. J. Jones, Treasurer, Mr. J. G. Jackson; Secretary, Mr. George M’Loughlin, 56, Hanover Street; and nine other members of committee.

Parliamentary and Law Proceedings.

PROCEEDINGS UNDER THE PHARMACY ACTS.

SALE OF NUX VOMICA BY AN UNREGISTERED PERSON.

The case of the Pharmaceutical Society of Great Britain v. White came before the Registrar of the Croydon County Court on Tuesday last. It was brought by the Society to recover a penalty of £5 from Mr. White for having sold a poison to an unqualified person within the provisions of the Pharmacy Act, 1868.

The defendant carries on the business of a general dealer at 17, High Street, Merton, and the case arose out of the sale by his daughter of a packet of “Woolf’s Vermic Poison,” which contains nux vomica.

Mr. Grey, barrister, appeared on behalf of the Society.

The defendant appeared in person, and submitted to judgment. He asked for time within which to pay the penalty, and said that he was ignorant of the fact of his daughter having sold the poison.

The Registrar pointed out that the defendant had been keeping open shop for the retailing of poison, and knew that he had the article in his shop.

Mr. Grey said the packet which was sold actually had the word “poison” on it in large letters in two places.

The Registrar gave judgment forthwith for the penalty and costs, but stayed execution on the terms of the defendant paying £1 a month.

ILLEGAL SALE OF STRYCHNINE.

On October 8, at Wandsworth County Court, the case of the Pharmaceutical Society of Great Britain v. Hollis and Co. came on for hearing. This was a summons taken out by the Society under the Pharmacy Act of 1868 to recover a penalty from the defendants for selling a poison, they not being qualified persons within the meaning of the Act. Messrs. Hollis and Co. are confectioners, carrying on business at 513, Battersea Park Road, and on August 7 last they sold a packet of Thorpe's rat and mouse poison, which, it was alleged, contained strychnine, one of the poisons scheduled under the Act. The defendants had paid the penalty into court prior to the hearing, but had not having done so within the prescribed time, application was made to the Registrar of the Wandsworth County Court on behalf of the Society for extra costs. The learned Registrar acceded to the application.

SALE OF POWELL’S BALSAM BY AN UNREGISTERED PERSON.

At the Wandsworth County Court, on Wednesday, the 10th inst., before his Honour Judge Lushington, the Pharmaceutical Society sued Robert Briggs, carrying on business as “Briggs and Co.,” at 55, Battersea Park Road, S.W., for two penalties of £5 each, for selling poisons contrary to the provisions of section 15 of the Pharmacy Act, 1868.

Mr. Grey (instructed by Messrs. Flux, Thompson and Flux) appeared for the Pharmaceutical Society; the defendant conducted his own case.

Mr. Grey, in opening the case, said the defendant keeps a drug store at 55, Battersea Park Road, and by his labels holds himself out to be a chemist. The action was brought to recover the two penalties in respect of the sale of poison contrary to the provisions of the Pharmacy Act. The article sold in this case was “Powell’s balsam of aniseed,” which, it would be proved contains morphia, a poison mentioned in the schedule to the Act. The Act is the 51 and 32 Vict., and its object, as laid down by Mr. Justice Hawkins,
is to prevent the danger likely to arise to the public from unqualified persons selling the various poisons mentioned in the schedule to the Act, under the name of "Powell's balsam of aniseed," and having regard to the fact that the said "Powell's balsam of aniseed" contains morphine, the Judge, and the defendants, not being the proprietors or manufacturers of the said composition, nor having any connection with it, are responsible for the sale of any such composition, and are liable for the consequences thereof.

The Judge (to the defendant): What is your defence?

Mr. Grey: I do not know, your Honour. I am brought here as regards Powell's balsam of aniseed. I am not the proprietor of Powell's balsam of aniseed. It is a patent medicine.

The Judge: What do you sell, or did you sell, it for sale?

Mr. Grey: I do not know. Who is the buyer?

The Judge: We shall hear that. You evidently do not know what your defence is.

Mr. Grey: Section 2 says: "The several articles named or described in the schedule (A) shall be deemed to be poisons within the meaning of this Act, and the Court of the Pharmacy Act.

The Judge: A preparation of morphine is a poison under the Act?

Mr. Grey: Yes. Then section 13 says: "The absence of the name of anyone from the printed register shall be evidence, until the contrary shall be made to appear, that such person is not registered according to the provisions of the Pharmacy Act."

The Judge: You do not say, I suppose, that you are registered, do you?

Mr. Grey: No. I say this is a "patent" medicine. Mr. Grey: Then section 15 says: "Any person who shall sell or keep open shop for the retailing, dispensing, or compounding poisons, or who shall take, use, or exhibit the name of any chemist, etc., not being duly registered, etc., "shall, for every such offence, be liable to pay a penalty of £5, and the same may be used for, recovered, and dealt with in the manner provided by the Pharmacy Act for the recovery of penalties under that Act." Then section 16, which I think is the one the defendant has now got his mind upon, says: "Nothing hereinbefore contained shall extend to or affect the business of a person w. o. m. or with the making or dealing in patent medicines." Now, Powell's balsam of aniseed has been the subject of a very good man's actions in the last two years, but I need only refer your Honour to the last one. That case (Pharmaceutical Society v. Armson) is reported in L.R. 1890, 2 Q.B. 134. The Society of apothecaries appealed to the Court of Appeal. There it was decided, following Piper's case, which was decided last year, that the prohibition in section 15 of the Act of 1888, dealing with the sale of poisons by other than registered chemists, is not confined to the sale of poisons in their simple state, but includes also poisons which form part of a compound.

The Judge: Even although it be a "patent" medicine? Mr. Grey: This is not a "patent" medicine.

The Judge: There is another phrase of "patent" medicine different from the legal phrase.

Mr. Grey: It is general amongst grocers to include under the title of "patent" medicines, not only those for which Letters Patent have been taken out, but also those which are secret remedies or nostrums. In law a "patent" medicine is only a medicine for which Letters Patent have been taken out. That was decided in Piper's case.

The Judge: This (Armson's) case deals with the very compound—"Powell's balsam of aniseed."

Mr. Grey: Yes; that case dealt with "Powell's balsam of aniseed," and it was then found to contain morphine to the amount of one-tenth of a grain to the fluid ounce. I will prove before you to-day that the two bottles in this case each contained one-fifth of a grain to the fluid ounce, or twice as much.

The Judge: I have read the judgments in that case. Mr. Grey: The defendant in this case was the actual seller of the two bottles.

Mrs. Sarah Partridge, examined by Mr. Grey: Did you on July 27 last go to 65, Battersea Park Road?

The Witness: Yes.

The Judge: What was it?—It was a chemist's shop.

The Witness: What did you ask for?—A bottle of "Powell's balsam of aniseed."

The Judge: Did he supply you?—Yes.

The Witness: What did you pay for it?—10½d.

The Judge: We have identified the bottle.

The Witness: Was there anything else round the bottle when it was served to you?—Nothing else.

The Judge: Did you go again in the following month?—On August 3.

The Witness: What did you ask for then?—A bottle of Powell's balsam of aniseed. I was served by the defendant.

The Judge: Was the bottle wrapped up in anything besides this?—No; not on either occasion.

The Witness: Were you desired to go and buy these bottles?—Yes.

The Judge: Who requested you to go and buy them?—A representative of the Pharmaceutical Society.

Mr. Grey: What did you do with these bottles?

The Witness: I took them home, and kept them under lock and key until I handed them over to Mr. Eastes on October 3.

The Judge: Did you keep them by you two months?

The Witness: Yes.

The Judge: Were they in the same state then as when you received them?

The Witness: Yes.

The Judge: Is the name of the defendant on the bottles?

The Witness: No.

The Judge: Cross-examined by Mr. Grey: On what date did you buy it?—On July 27.

The Witness: What time of the day was it?—About seven o'clock in the evening.

The Witness: What day was it?—I believe it was on a Friday.

The Judge: According to the date it appears to be a Saturday?

The Witness: Was it about a quarter to twelve?—No.

The Judge: Your Honour, I believe, has the bottle here.

Mr. Grey: The witness wrote on it as soon as she got home the actual date when she bought it.

The Judge: The date on the bottle appears to be July 24.

Mr. Grey: I think we have a book showing the date of the purchase to be the 27th.

Mr. Grey: Did you receive on October 3 two bottles from the last witness?—I did.

The Witness: In what condition were they when you received them?—They were sealed.

The Judge: Was the medicine stamp on each bottle broken or unbroken?—Unbroken.

The Witness: Did you analyse the one taken on July 27?—I did.

The Judge: What is it called?—"Powell's balsam of aniseed."

Mr. Grey: Did you analyse the bottle bought on August 3?—Yes.

The Judge: Did you find morphine in that bottle, and to what
extent.—The same extent—one-fifth of a grain to the fluid ounce.

The Judge: What effect would it have if it were administered to a child?—It would be fatal to a young child.

Cross-examined by Mr. Briggs: You say the stamp was unbroken?—It was unbroken.

This being a “patent” medicine, how am I to know the contents of the bottle?—There have been many cases relating to Powell’s balsam of aniseed.

The Judge: Perhaps you are bound to know.

Mr. Briggs: If you look you will see that it merely states “Powell’s balsam of aniseed.”

The Judge: Very possibly you did not know it was poison.

Mr. Briggs: I did not;

Mr. Grey: That is my case. I put in the register.

Mr. Briggs: If I sold this poison it was in ignorance. It is a “patent” medicine, and I have got a patent medicine licence.

The Judge: All that is admitted. Piper’s case was not Powell’s balsam.

Mr. Grey: No, that was chlorodyne.

The Judge: Is the regular course to impose a penalty of £5?

Mr. Grey: That is the amount fixed by the Act.

The Judge: Is the full penalty exacted in all cases?

Mr. Grey: There is no discretion as to the amount?

The Judge (to the defendant): I do not know whether you know the law, but you are bound to know the law. I should think in your business the law was well understood by this time, because in Armon’s case the very same point was decided, and the very same article, “Powell’s balsam of aniseed,” was dealt with. You call this a “patent” medicine, but you know it is not a patent medicine. There is no patent for it; in fact, we know it is only what is called a proprietary medicine. It may be that you did not know what it is made from, but still that is no answer; it is no protection to the public if you sell poison not knowing it to be poison.

You are liable if you sell any poison provided against by the Act. Here you clearly did sell this “Powell’s balsam of aniseed,” and it is quite clear that it was a preparation of morphine, and contained morphine to the extent of one-fifth of a grain to the fluid ounce. The case is certainly against the schedule to the Act. In this case you are liable, and I must impose a penalty of £5 in each case.

Mr. Grey: I ask for costs under scale A. The same defendant was before you as late as April 21, and the same penalty was imposed then, but it seems to have done him no good.

The Judge: I did not know that.

Mr. Briggs: It was not a “patent” medicine then.

Mr. Grey: I ask for the costs under scale A.

The Judge: Yes.

Mr. Briggs: Can I appeal against this?

The Judge: You have nothing to do with that. I may tell you that a case has been decided by the Court of Appeal with reference to this very “Powell’s balsam of aniseed” sold under circumstances exactly like this, except that perhaps your case may be somewhat stronger, as the bottles in your case contained a larger quantity of poison.

ILLEGAL SALE OF WEED KILLER.

The case of the Pharmaceutical Society v. Moore also came before his Honour Judge Lushington at the Wandsworth Court on Wednesday, the 10th inst.

Mr. Moore appeared for the Pharmaceutical Society.

The defendant appeared in person.

Mr. Grey said: This is another action for a penalty for the sale of poison, but in rather a different form.

The defendant in this case is a nurseryman, carrying on business at 261, Upper Richmond Road, Putney, and on the 27th of July he sold a can containing a portion of “Smith’s Weed Killer.” That gallon of “Smith’s Weed Killer” was found to contain as much as 2½ lbs. of arsenic, which, I need hardly say, is enough to kill thousands of people. I will not refer to the Act again, but I merely say that with regard to the sale of arsenic, even if chemists sell it, they have to go through a great number of forms in order to know whom it is sold to, and so on.

The Judge: You need not trouble yourself about that.

Mr. Grey: They have to give the address of the person to whom they sell, etc. In this case the “Smith’s Weed Killer” was sold without any question whatever. Arsenic is the first poison mentioned in the schedule.

Mr. John Partridge, cross-examined by Mr. Grey: Where do you live?—At Brixton

The Judge: What are you?—I am a commission agent.

I suppose you were directed by the Pharmaceutical Society to make this purchase?—Yes.

Whom did you see?—I saw the defendant.

Mr. Grey: What did you ask for?—A gallon of weed killer.

The Judge: Is that a well-known thing?—Yes.

Mr. Grey: How was that supplied to you?—In a tin.

Was it put into the tin by the defendant?—Yes.

What from?—From a larger tin, containing perhaps six or seven gallons.

What did you pay for it?—2s. 3d.

[Receipt produced and identified]

What did you do with it? Did you hand it over to Mr. Eastes for analysis on Oct. 3?—Yes.

In whose possession was it until Oct. 3?—In my possession under lock.

Mr. Ernest John Eastes cross-examined by Mr. Grey: Did you receive the can which is before you?— I did.

Did you analyse the contents of that can?—I did.

What did you find it contain?—I found that it contained arsenic.

How much?—Nearly 2½ lbs.

The Judge: How many persons would that poison?—I should think 8,000 at the smallest computation.

The Judge (to the defendant): Do you not say you are registered under the Act?

Mr. Moore: No. I will state the facts. Some time ago I had been asked by one of my employers to get this weed killer, and I got it and used it. Being a small gardener it killed all the weeds, but my workmen said it took their work away, and I put it away in a cupboard and did not use it. Mr. Partridge came and said, “Do you keep Smith’s Weed Killer,” and I said I had some, and searched about and found the can and put a gallon into a can for him. He asked how much it was, and I did not even know the price, but I charged him 2s. 3d. He asked for a memorandum, and I gave him one. Mr. Partridge went away, and in the course of a few weeks I received a letter from a firm of solicitors in London, saying that I had infringed the Act by selling a poison. I was startled, and thought they had made a mistake. Then I received another letter, saying that I had infringed the Act by selling a weed killer containing poison. I knew nothing about the Act, I have never heard there was one, and I do not keep a shop in any way; I simply had this stuff by me. I have had to give up business because there has been nothing doing, and I am now seeking a situation. I sold it as a gardener innocently.
The Judge: How did you get it originally?
Mr. Moore: I got it about five or six years ago on the suggestion of a customer. If I had been told I must not sell it I should not have thought of doing it; I think it is very hard to impose a penalty on me under the circumstances.

The Judge: I understand you to say, Mr. Grey, that the words "shall be liable to pay" imply a duty on the Judge to impose the penalty if it is due? I have no discretion.
Mr. Grey: No, you have no discretion.

The Judge: I suppose your Society has a discretion as to whether they shall enforce it or not?
Mr. Grey: I am not sure of that. The Society is bound to take the proceedings. I should like to call your attention to this fact, that there have been a number of cases of poisoning by weed killers.

The Judge (to the defendant): I am bound to inflict upon you a penalty of £5. As far as I am concerned, I am prepared to accept your statement that you did not know it was a poison, and that you came by it in the way you have stated; but still that will not relieve you from your obligation to the public. It is very necessary for the public that these proceedings should be taken.

Correspondence.

BRAGANTIA WALlichii.

Sir, With reference to Mr. Hooper's paper on Bragantia wallichii (Pharm. Journ., Sept. 22, p. 231, and Dr. Masters' letter on the same subject, Pharm. Journ., Oct. 6, p. 290), I may perhaps be allowed to add a few words towards clearing up the mistake that has surrounded the section of stem received by Dr. Masters from Dr. Cleghorn, at the time the former wrote his paper in the Journal of the Linnean Society, vol. xiv, p. 487, which is referred to by Mr. Hooper, who says that the sketch of the section in the Linnean Journal shows a very eccentric arrangement of the wood, with irregular zones extending laterally, indicating a plant of a scanty habit, and quite different from the stem of true Bragantia wallichii. Dr. Masters' modesty allows him only to say in his communication to the Pharmaceutical Journal "that Dr. Solereder has shown that the stem I received under the name of Bragantia wallichii cannot belong to that genus, nor even to the Aristolochiaceae," but he does not say that in his original description of it in the Linnean Journ he pointed out that "the arrangement of the wood is here totally unlike that of Aristolochia." He further gives a minute and accurate description of the wood structure which it may be well to reproduce here as further proof of its dissimilarity from any Aristolochiaceae, thus: "A transverse section shows a primary cylinder of wood surrounding a pith whose cells are filled with starch grains, and which is begirt by a dense layer of hard, dark-coloured liber, whose cells are completely filled with woody deposit. The wood itself is soft, and consists exclusively of long wood cells, interspersed among which are porous vessels. Outside this primary cylindrical portion are arranged in layers, one or two other, imperfect some of wood and bark—imperfect in that they appear not wholly to surround the original cylinder but to spring from its sides somewhat as a watch-glass does from a watch. These concentric layers differ also from the original cylinder. In the first place they have, of course, no pith, the wood being applied immediately upon the cortical or liber layer of the zone which they surround. Again the medullary rays in the primary cylinder are small, and their component cells are only slightly, if at all, thickened by woody deposit in their interior, while in the succeeding layers the medullary rays are thick, dense, hard, and dark brown in colour, being in fact continuous with the bands or zones of liber cells which separate the wood zones. The portion of stem thus described having been presented to the Kew Museum by Dr. Masters, I was led some time since to examine it, and its similarity was so close to that of Gnetum that upon comparing it with the wood of that genus no doubt was left as to the Gnetaceae being its proper position, and very little doubt indeed that its accurate identity is with Gnetum scandens.

SIR,—In reference to Dr. Masters' letter last week (p. 290), pointing out that the stem he received from Dr. Cleghorn as Bragantia wallichii was subsequently shown by Dr. Solereder to be not an Aristolochia at all, it may be interesting to add that I received this morning a postcard from Dr. L. Radlkofer referring me to a paper on Bragantia wallichii, by Dr. Solereder, in the 'Bull. Herb. Boiss.', II., 'No. 5 (1894) p. 854, in which the latter has proved that the stem in question is that of a species of Gnetum. This genus, it will be remembered, was shown by Mr. W. Kilborne at the meeting of the Pharmaceutical Conference at Oxford this year, to yield a stem very like that of Pararea brucei. The resemblance of the supposed Bragantia to Aristolochia is not conspicuous, but the stems had always been noticed by Dr. Masters. To the naked eye the difference between the reverse section of an Aristolochia and a Gnetum or Pararea brucei is evident in the fact that Aristolochia does not possess conspicuous concentric rings. It is fortunate, therefore, that Mr. Hooper gave an illustration of the drug that he examined. There are, of course, histological differences between the genera Aristolochia and Gnetum, which are fully explained in the paper by Dr. Solereder, referred to by Drs. Masters and Radlkofer.

E. M. Holmes.

Diary of the Week.

SUNDAY, OCTOBER 14.

Chemists' Assistants' Association.
Exursion to Chingford and Epping Forest.

WEDNESDAY, OCTOBER 17.
Western Chemists' Association (of London), at 8.30 p.m. Annual Meeting at the Westbourne Restaurant.

THURSDAY, OCTOBER 18.
Chemists' Assistants' Association, at 8.30 p.m. "The Duties of the Pharmaceutical Society as an Educational Body." Discussion to be opened by E. H. Gane.
Midland Pharmaceutical Association, at 8.30 p.m. Inaugural Meeting at the Midland Hotel. Address by the President, Mr. R. Darton Gibbs.
Glasgow and West of Scotland Pharmaceutical Association.
Address by Dr. D. C. McVail.

FRIDAY, OCTOBER 19.
Quellet Microscopical Club, at 8 p.m. Ordinary Meeting.

SATURDAY, OCTOBER 13.
Pharmaceutical Football Club.
Practice Match at Wormholt Farm, at 3.15 p.m.

Communications, Letters, etc., received from Messrs. Allen, Bennett, Clark, Coupland, Cracknell, Jackson, Lunan, Marshall, Martin, Miles, Newsholme, Thompson, Warrell, Wright.
Weights and Measures.

BY D. B. DOTT.

The question of introducing the metric system of weights and measures into the Pharmacopoeia is now prominently brought forward, and deserves full discussion and consideration. The introduction of the metric system is recommended on two distinct grounds: first, that of its essential superiority to the British code, and secondly, on what may be called the ground, that because other nations have adopted the system, it is convenient that we should do so also.

It is too much the fashion to speak as if the British system were everything that is bad, and the metric everything that is good. It may readily be admitted that the adoption of the metric in place of the avoirdupois system would be an advantage, as it would greatly simplify calculations, yet its introduction would have other drawbacks besides the trouble involved in making the change.

I remember Sir Frederick Bramwell, from an unprejudiced point of view, objecting to the decimal system because it did not conveniently lend itself to subdivision by halves. No doubt there is something in that objection. By the unfortunate habit of fixing the size of the metre from a proportion of the earth's meridian, a standard has been got which is inconveniently long. As Professor Tait says:—

"Any cloth merchant will tell you that." Similarly, the kilogramme and litre are inconveniently large.

To many minds, also, the nomenclature, however systematic, is clumsy and long-winded. All our English names for weight and measure are short, mostly monosyllabic, unlike "centicentimes," while the very similarity of such names as decigramme and dekalitre suggests confusion. It also seems worthy of note, that it is easier for a man to bear in mind such a quantity as 3 lb. 13 ozs. than, say, 1728 grammes (see U.S. Pharmacopoeia). But the chief weakness of the metric system is just in the same fact in which consists its strength, viz., that it is a decimal system, dependent wholly for its accuracy on the position of a point. It is, indeed, not a system of different denominations, as grammes, but a system of one denomination multiplied or divided by the placing of a point. I am aware it has been denied that there is any more liability to error in the one system than the other. That is a matter of opinion. From a pretty constant experience of both methods for twenty years, I think there is a decided balance of accuracy in favour of the British system. A man is more apt to write '01 gramme instead of '001 gramme, than he is to write gr. i. instead of gr. j., and when the writing is preceded by a calculation there is even greater liability of decimal point going wrong. I am, therefore, of opinion that for prescribing and dispensing the British system of weights and measures is to be preferred, while for analytical work the metric is more convenient.

The British system, as we now have it, has one serious defect, which is noted in the Pharmacopoeia itself. "It must be admitted that the absence in the present system of any denomination of weight between the gram and the avoirdupois ounce of 5 grams is a mere fact that the ounce is not a simple multiple of the gram and grave defects." It might be added that the difference in volume between the minim and grain measure is an anomaly and absurdity. The old troy weight, or that modification of it which used to be called apothecaries', is a system complete and perfect in itself. Who it was that conceived the idea of mixing up two different systems and so producing confusion I do not know, but it was not a happy thought. Surely the trifling trouble of keeping two sets of weights, one for dispensing purposes and one for ordinary trade transactions, would be preferable to working with a hybrid mixture which is no system at all.

It is proposed that in the new pharmacopoeia the proportions of ingredients should be given in the metric as well as in the British system. Of course, the present method of stating "parts" and "fluid parts" is practically the same thing. In the volumetric tests it would be scarcely worth while to refer both to grain measures and cubic centimetres. It would probably be sufficient to give only the metric equivalents. In the present pharmacopoeia the strength of a preparation is sometimes indicated by percentage, sometimes by grains in a fluid dram, or some other amount. It would be distinctly better to have an absolute standard of a fluid dram, or in the case of liquids it might be grammes in 100 C.c. For the convenience of prescribers it is quite appropriate to state in the account of a preparation the number of grains of the active ingredient in the fluid ounce; but under "characters and tests" the strength should be systematically stated by percentage.

Reserve Materials of Plants.*

The metabolism of plants consists of two essentially different processes, the simple bodies originally absorbed being worked up, at the cost of a great expenditure of energy, into bodies such as animals live on, and the actual nutrition of the organism commencing subsequently to this formation of elaborated materials. The tendency of plants is to accumulate stores of material on which their protoplasm may subsist, and from which their new substance may be constructed, and a great part of their metabolism is directed towards the accumulation of these "reserve materials" in their tissues.

Besides the reserve materials laid up in seeds, tubers, and other reservoirs, there is a circulating store, flowing sometimes in one direction and sometimes in another, which consists of the same materials as the quiescent reserves, but fitted for the immediate use of the living substance. Whilst the carbohydrates of the reservoirs are mainly starch or inulin, those of the circulating sap consist of sugar or vegetable acids derived therefrom. Again, the nitrogenous bodies of the seed are usually either definite grains or collections of amorphous proteids, but those of the sap are mainly diffusible proteids or amide bodies largely derived from them. In seeds, tubers, bulbs, corms, fleshy roots, and stems, there is found an almost permanent deposit of food material; whereas in medullary rays and cells of vascular tissue, in sieve tubes and laticiferous vessels, the material is laid down for only brief periods, ready for an

* Abstract of a paper by Professor J. Reynolds Green, M.A., Sc.D., in Science Progress for October.

VOL LIV. (Third Series, Vol. XXV.), No. 1269.
almost immediate demand on the part of living cells. The temporary stores are as a rule of a more easily transformed character than the more permanent ones.

Nitrogenous reserve materials, wherever found, are largely met with in the shape of some form of proteid matter. Numerous vegetable proteids with very curious reactions have been shown by recent investigations to be of the same nature and similar composition to proteids of the animal body. Other nitrogenous compounds, chiefly confined to the fluid sap in the living cells, are grouped together as amides. They include asparagin, glutamin, rhizamin, tyrosin, and other crystalline bodies. Some amount of nitrogenous reserve materials may also be found in some of the glucosides, such as amygdalin and myrosin.

Non-nitrogenous reserve material is mainly carbohydrate, such as starch and its derivatives, cellulose, sugars, inulin, and glycogen. Next in importance come the glucosides, whilst fats and oils are of common occurrence in many fruits and seeds. Then comes tannin, phloroglucine, and alkaloidal matters, which are of uncertain nutritive value, and, lastly, small accumulations of mineral matter often occur associated with proteid deposits.

The proteid substances are naturally of primary importance. They occur in large quantities in many seeds, are easily isolated, and are generally spoken of as aleurone grains. Pfeiffer, in 1872, attributed their first formation to the influence of the mineral constituent—calcium oxalate or calcium and magnesium phosphate—with which they are associated. More recently Rendle has argued that the process is one of true secretion, and not a mere mechanical precipitation. Beirung, in turn, opposes the secretion theory and favours Pfeiffer's view. The hypothesis of protoplasmic secretion, however, has probably most to be said in its favour.

With regard to the composition of these proteids, Weyl gave the names of vegetable myrosin and vegetable vitellin respectively to two globulins, coagulating at different temperatures (65° to 60°, and 73°), which he extracted from various seeds. Vines confirmed Weyl's results in the main as to the composition of aleurone grains, and discovered in some seeds another proteid—an albuminate or derived albumin. The crystalloids in the cells of potato tubers belong to Weyl's vegetable vitellin, and Zöller has also found in the potato some vegetable myrosin. The occurrence of proteid in similar forms has also been indicated by several other workers.

The latex of plants has been proved on investigation to contain various proteids. Thus, Martin has found two well-defined albumoses, a globulin, and an albumin, in the latex of Cerica pepaya; and Green has shown that the latex of Paramecia glandulifera contains a peptone-like body, capable of dialysis and convertible into peptone by the action of pepticin. A similar substance occurs in Brosimum galactodendron, the "cow-tree" of South America. The cortex of the stem of the Manihot contains a globulin, the succulent tissue of the lettuce an albumose, and the underground parts of asparagus an albumin. The proteids found in latex and various succulent tissues are not in the form of aleurone grains, however, being either in solution or packed away in an amorphous form in the meshes of the protoplasm.

True peptone occurs in the germinating seeds of leguminous plants and cereals, being probably a stage in the transformation of the resting reserve material to amide bodies, which are transported from the food reservoirs to the seats of active growth.

The reserve proteids proper, then, are to be regarded as non-diffusible, granular or amorphous bodies, soluble with difficulty, and almost without power of dialysis. There are several albumoses, two groups of globulins, and albumins, whilst in regions where storage is not so evident are found members of the peptone group, which give characteristic reactions, and are capable of dialysis.

Practical Systematic Botany.

(Concluded from page 293.)

Having determined the class, the student may proceed to find out the sub-class. If the plant is evidently dicotyledon, he must ascertain whether there is only one row of leaves in the flowers (Apetalae), two rows in the inner rows of the flower (Monocotyledoneae), or two rows, the inner rows consisting of separate pieces (Polypetalae). If the last, he must further determine whether those of the inner row (petals) are attached to the thalamus (Thalamiflorae), or to the calyx (Calycoflora). If the plant apparently belongs to the Apetalae, he must make sure that it is not an anomalous plant of the other sections, such as the clematis, in which there is only one row of leaves in the flower, and they are coloured. In this plant the stamens are numerous, and numerous carpels are present. In Apetalae, if the numerous stamens are present the carpels are absent. As the Apetalae are not a natural section, although a convenient one, help should be obtained from a botanist when a flower possesses only a single row of leaves, and the student fails to find it mentioned in the appendix of exceptions in the 'Botanical Note-book.' If the plant proves to be a monocotyledon, the student's task is much easier. The flower will belong to one of three sections. In the one, the parts of the flower are either in a multiple of three, as in the lily (Papilionaceae), or the coloured parts are absent, as in the grasses (Gramineae). In the other two, the stamens and carpels being enclosed between two small leaves (bracts), or the flowers are arranged densely together without either calyx or corolla, and the whole enclosed in a large membranous leaf (spathhe), as in the Arum (Spadiflorae). Having determined to which of the above groups the plant belongs, he may then proceed to consult a chart of the principal natural orders. If he commences with ordinary medicinal plants, these will certainly come under some one of the twenty-eight orders of which a knowledge is required by pharmacists. If these are not obtainable, he may have to consult the second chart is the 'Botanical Note-book,' but this should not be done until it is evident that the plant does not belong to one of the orders in the first chart. Unless the plant agrees with all the characters given under the natural order, it may be decided that it does not belong to it, and the student may pass on to the next natural order, unless there is strong reason for supposing that the plant is an exceptional one. For instance, the marsh marigold (Caltha) has a family likeness to the buttercup, but it is not the same plant in every respect.
having numerous hypogynous stamens and separate carpels, but it has only one row of leaves in the flower. Strictly speaking, therefore, it would be put in the Apetalsae. In a difficulty of this kind, reference should be made to the appendix to the chart, where these anomalous plants are mentioned.

Having settled the natural order, if it is desired to identify the species, the best plan is to write out a description of the plant on a schedule and then to compare it with the description of the plants given in a Flora, first comparing it with the characters given under the genus, then under those given for the sections of the genus, and lastly with those given under the species. Although the process seems a lengthy one, it is the quickest in the end. If the plant be not examined in this methodical and business-like manner, as much as an hour may be wasted over a single plant, and the student even then left in doubt whether or not he has rightly named the plant. To determine the name of a plant easily it is absolutely necessary to gather the whole of the plant if possible, and if not, the fruit and root leaves should never be neglected, as these in certain cases are distinctive. Thus, in the Umbelliferae and Cypselaeae it is almost impossible to name a plant in which the fruit is not fully developed, and time is only wasted in making the attempt. It will be observed that, for the purposes of the examinations, the specific name is only required in the case of a comparatively small number of medicinal plants, and that it is much more important to the student to be able to refer a plant to its natural order and genus. It is too commonly supposed that to know the names of plants is to be a botanist, which is very far from being the case.

For the apprentice resident in a city, the best method of forming a good idea of a natural order will be to go to a botanical garden and ask for a few of the typical plants of any of the natural orders required, and to compare them with each other. Thus, taking for instance the Ranunculaceae, let him observe the general characteristic features of the order (reduced to a minimum of two in the chart No. 1 in the 'Botanical Note-book'), and examine as far as possible the plants diverging from the type. Thus, supposing the buttercup to be the type of the Ranunculaceae, having numerous hypogynous stamens and separate carpels as the leading features, let it be compared with the soapwort, in which the petals and sepals are irregular; with the heptapetes, in which the apparent calyx is a three-leaved involucre; with the anemone, in which the calyx is coloured, the involucrum removed lower down the stem, and the corolla absent; with the delphinium, in which the calyx and corolla are spurred; with the hellebore, in which the petals are tubular and the calyx coloured; with the peony, in which the calyx is persistent; and with the clematis, in which the leaves are opposite. In all these he will find the leading characters present, viz., numerous hypogynous stamens and separate carpels. He will thereby understand that there may be as much variation in the characters of the plants of a family as there is in the members of a human family, which all present some traits in common. If he be fortunate enough to obtain a specimen of "Love in a Mist," or the "Devil in a Bush," as they are popularly called, he will understand how one natural order is linked on to another, since the carpels in this genus are partly united, showing an approach to the Papaveraeae.

For determining the names of British plants a very portable and useful book is Hayward's 'Botanist's Pocket Book' (G. Bell and Son, London), by means of which the names of plants can be honestly found out. In cases of difficulty only, the 'Illustrations of the British Flora,' by Fitch and Smith (L. Reeve and Co.), may be referred to; but to identify a plant by a picture is not to learn botany.

A few words in conclusion concerning the mode of examining fresh flowers may be useful. Large flowers should always be used in the beginning, and one flower only taken in the hand. One side of the flower should be held in the left hand, and the parts of the flower removed first from the opposite side with the right hand. If the flower be tubular, it may be slit open from below and rolled open by a movement of the finger and thumb, so as to see the attachment of the petals and stamens. To examine the ovary the oldest flower present which has lost its corolla should be chosen, as in it the ovary will be larger. A thin transverse section of the ovary should be made and laid on a dark surface, when the arrangement of the ovules will be seen. If the flower is minute, it must be dissected with needles in suitable* holders under an ordinary magnifying glass placed on a support, such as a test-tube holder or a miniature retort stand, or preferably under a cheap dissecting microscope, in which the mirror proves a great advantage.

**NITRITES OF THE PARAFFIN SERIES AND THEIR PHYSIOLOGICAL ACTION.†**

An investigation was commenced three years ago, in the Research Laboratory of the Pharmaceutical Society, and the Pharmacological Laboratory of the University of Aberdeen, in order to throw further light on the mode of action of the paraffin nitrites when introduced into the animal organism, and observations were made regarding the action of eleven such nitrites in a pure state on blood pressure, pulse, respiration, and striated muscular fibre. The compounds employed were as follows:—

<table>
<thead>
<tr>
<th>Name</th>

* Obtainable of C. Baker, Holborn, and probably other dealers.

† Abstract of a paper by Dr. J. Theodore Cash, F.R.S., and Professor Dunstan, F.R.S., in the *Philosophical Transactions of the Royal Society of London.*
dered it possible to compare the action of a series of substances containing an atom of nitroxylic NO₂ united, respectively with CH₂, C₂H₅, C₃H₇, C₄H₁₀, and C₅H₁₁, and to determine the modifying influence exerted by those radicals upon the characteristic action of nitroxylic.

The first portion of the paper embodying the results deals almost entirely with the action of the various nitrites on blood pressure, and with the special apparatus used in its study. The latter part has reference to the action of the same compounds in producing contraction of striated muscle, and concludes with a chemical discussion of the whole of the results obtained.

When the effects of primary, secondary, and tertiary nitrites, alike in composition, were compared, it was found that the secondary compound had a more powerful influence generally than the primary, and the tertiary than the secondary. The more marked effect of the nitrites with the largest molecules but containing least nitroxylic is supposed to be due to their decreased chemical stability; and the greater power of secondary as compared with primary, and of tertiary as compared with secondary nitrites, is attributed to their respectively greater instability, rather than to the number of methyl groups attached to the carbon combination of the nitroxylic group.

OPium TRADE OF MACAO, CHINA.

Opium is, as hitherto, the most valuable article of import and export. It is imported crude, and exported mostly prepared. The opium farmer, however, is the sole person who enjoys the monopoly of boiling down the drug; but other parties have the privilege of importing and exporting it in a raw condition. During last year no agreement was again concluded with the opium farmer in Hong-Kong, so that the San Francisco and Australian steamers have had to call at Macao to ship their valuable cargoes. This new order of things is far more economical than the former régime, when the opium farmer had to be paid a heavy sum for the permission of passing the prepared opium through his preserves in Hong-Kong. The statistics before me for the first half of 1893 show a decrease both in the import and export of opium. Nor can the second half of the year have been more satisfactory, as even assuming that heavy stocks had to be worked off, the general opinion is that a reaction would have taken place before long had not the falling exchange completely paralleled this trade. For the present, however, native opium has not received any impetus nor come into favour. In fact, little, if any, finds its way as yet so far south. Neither could smuggling be held responsible for the decrease, for though smuggling still continues, especially in the case of junks from Singapore, as they bring back opium in lieu of remittances, now that the rate of exchange is so uncertain and low, it cannot have assumed such vast proportions as to have diverted any so very considerable quantity of opium from the legitimate channel of importation.—Consular Report.

CUBEBS AND ITS ADULTERATIONS.

The microscopical investigation of cubeb and its adulterations, carried out by Dr. A. De Wevre during the spring of last year in the Museum of the Société, and at the Jodrell Laboratory in Kew Gardens, have at length been published in the Annales de la Société Royale des sciences médicales et naturelles de Bruxelles, tom. 3, from which the following abstract is taken. By the courtesy of the editor we are able to reproduce the figures drawn by Dr. De Wevre to illustrate his brochure.

The first chapter contains a history of the drug during the present century. The first notice of an adulteration of the drug seems to have been in 1837.* In 1882, J. Murray ('Drugs of Science') pointed out that the fruits of Piper canum were supplied in commerce instead of those of P. cubeba. In 1883, Professor Baillon mentioned that P. ribesoides and P. lowry were sometimes substituted for cubeb. In 1885, Holmes and Gravil† directed attention to a spurious and injurious cubeb with a mace-like odour, which was at the time supposed to be P. orossipes, Korth., and a microscopical examination of it was made by Kirkby,‡ and a chemical one by Elborne and Wilson.§ In the same year the occurrence of Daphnium cubebae in English commerce as a substitute for cubeb was recorded, and the fruits were examined by Braithwaite and Farr.¶ In 1886, MacEwan** directed attention to the presence of the fruits of a Rhamnus, black pepper and, pepper stalks, and of the flowers of an Alpinus, in cubebes imported from Bombay. In 1887, Kirkby‖ gave the histology of a large cubeb which was offered as a substitute for the genuine drug.

In the same year the presence of immature cubebes in the commercial article was noticed, and it was found that these would not give the iodine reaction that the mature fruits afford, and it was suggested that this

‖‖ Pharm. Journ., [3], xviii., p. 369.
peculiarity might be due to the presence of glycoaomic acid, which, according to Messrs. Brunner and Chouard, occurs in unripe fruits, and forms with iodine a soluble and colourless compound. * In 1889, Lowe observed that in some immature cubebes the endocarp was absent and the embryo rudimentary. In the same year M. Brunotte recorded the occurrence as an admixture with cubebes of the fruits of Eriodendron. Cubeba ciusii, Rhamnus, and pimento. † Gehe also described four forms of cubebes occurring in the ordinary commercial article. ‡ In 1892, Dr. Trenb pointed out in St'Land's 'Plantentaun' that the natives of Java recognise three varieties of the cubeb plant, which they call respectively Rinoes katoenjfar, Rinoes badak, and Rinoes tjaroekock. In

1. Piper cubicaba.—By a microscopic examination he has confirmed the fact, observed by Holmes, that the Rinoes katoenjfar is identical with the genuine cubeb, of which the following are the chief characteristics: The stem and leaves are furnished with simple uniseriate pluricellular hairs, and the nerve of the leaf has a planoconvex section (Figs. 1 and 3). The section of the fruit has the structure ascribed to it by Kirkby and others, the principal points being the prismatic shape of the solrenchymatous cells of the endocarp, which are arranged radially in a single row, and the compressed parenchymatous cells of the mesocarp, of which there are usually only four rows (Fig. 4). The fruit is 4–5 mm. in diameter, and the pedicel is 5–7 mm. long. The fruit gives a carmine red colour with strong sulphuric acid. Dr. De Wevre could not confirm Dr. Tschirch’s statement that the walls of the oil glands are lignified. In the powder the prismatic stone-cells of the endocarp should occur, and comparatively few tracheides; these latter are more abundant if many of the pedicels are present. If iodine gives a blue colour it is necessary to determine if this is due to the small polygonal starch grains, without hilum or centric rings, or to particles of cellular tissue. In the latter case rhamnus fruits may be suspected to be present.

Among the samples in the Museum of the Society, slight differences were observed. In those from the Bagelen and Cheribon and Djohokarta districts in Java, the plants had shorter hairs; in some the endocarp cells were longer or broader, and the number of rows of compressed cells in the mesocarp varied slightly.

2. Rinoes badak.—This variety of the cubeb differs from Rinoes katoenjfar in the absence of hairs on the stem and leaves, and in the fact that there is a layer of thick-walled cells under the upper as well as under the lower epidermis. The fruit bears a very strong resemblance to the genuine cubebes, but the cells of the mesocarp form eight to nine, or even twelve rows, and sulphuric acid gives a yellow brown or orange tint with the crushed fruit. Dr. De Wevre identifies the cubebes with a macy odour described by Kirkby (Pharm. Journ., [3], xxv., p. 653), and the Piper erasistes of Elborne and Wilson, with Rinoes badak (which, however, Holmes refers to P. sumatranaus). Dr. De Wevre, from the examination of specimens in the Kew Herbarium, has arrived at the conclusion that the Rinoes badak is not identical either with P. erasistes, Korth., or P. sumatranaus, Miq.

Rinoes badak appears to vary within certain limits. A specimen from the Soerabaya district shows a slight difference in the fact that the sub-epidermal stone-cells do not form a complete ring, but are separated by wide interspaces, and the endocarpic stone cells show a tendency to become polygonal.

Another sample from the Soerakarta district approaches Rinoes badak in the glabrous leaves and stems, in the mesocarp presenting six or seven rows of cells, and in the endocarp having polygonal or rectangular stone-cells in addition to the prismatic ones, but the fruit gives a carmine-red tint with sulphuric acid.

3. Piper cubicaba, var. erasistes.—Under this name Dr.

* Pharm. Journ., [3], viii., p. 461; xvi., p. 917.
† 'Thése de l’École supérieure de Pharmacie de Nancy.'
‡ Pharm. Journ., [3], xx., p. 243.
§ Pharm. Journ., [3], xxii., pp. 181, 784.
De Wevre describes a fruit 7 mm. in diameter, 7 mm. long, with a pedicle 11 to 15 mm. long, or about twice as long as the fruit, and flattened throughout, and states that it has the colour of mace, and a more bitter and less burning taste than true cubeb; sulphuric acid gives with the crushed fruit a brown coloration only. The illustration he gives is almost exactly identical with that given by Kirkby, except that in the latter there are scattered groups of stone cells in the epicarp, and the mesocarpic cells are in eight to ten rows. The endocarpic cells are polygonal and arranged in two rows, and the mesocarpic cells are in six or seven rows (Fig. 5). Dr. De Wevre has examined a cubeb fruit in the Kew Herbarium, which had been determined by Miquel himself as Cubeb officinalis, Miq. This specimen, however, has an endocarp approaching to that of the P. cubeba var. crassipes,

Fig. 5.—Fruit of P. cubeba, var. crassipes, transverse section.

De Wevre, the endocarp being formed of polygonal, somewhat flattened cells, a little elongated tangentially, and arranged in two rows. With sulphuric acid the fruit gave a brown red coloration. He suggests that it may perhaps be the Rinoe japonicum of Dr. Treub.

(To be continued.)

IMPORTS OF ASAFOETIDA INTO SIND AND BRITISH BALUCHISTAN.

In a recently issued “Return relating to the External Land Trade of the Province of Sind and British Baluchistan for the official year 1893—94,” it is stated that the trade in asafoetida rose from fifteen maunds, of the value of 1800 rupees, in the year 1892—3, to 197 maunds, of the value of 23,640 rupees, in the year just ended, being an increase of 182 maunds, and a value of 21,840 rupees, wholly in imports from Kandahar. In drugs of other kinds the import trade declined to the extent of 340 maunds, valued at 714 rupees, chiefly from Kandahar.

CITRIC ACID IN CANE JUICE.

The following account of the appearance of citric acid in the process of sugar manufacture is given in a letter from Mr. Edmund C. Shorey, of Kohala (Hawaiian Islands) :

“An examination of the organic matter showed that the chief constituent was citric acid, and this combined with lime as calcium citrate formed the body of the scuad. I have by decomposing the scale with sulphuric acid, forming sulphate of lime and setting free the citric acid, filtering and evaporating, obtained quite large crystals of citric acid. There are several other organic acids present, the nature of which I have not yet determined, but the citric acid predominates, and is the one that gives most trouble, owing to the property of calcium citrate being more soluble in cold than in hot water, and consequently of being precipitated from a boiling solution. Unless most of the calcium citrate is precipitated in the triple effect it will be in the vacuum pan, and going into the first molasses makes trouble with the second sugar. Here it shows itself as a fine grain or cloud, much like ‘false grain’ in appearance, and having the same effect in centrifuging, preventing the purging of molasses. A strike of No. 2, which cannot be dried owing to the presence of calcium citrate, will generally dry when cold, enough of the calcium citrate having entered into solution to allow the molasses to go free. I have seen this citrate of lime present in No. 2 sugar to the extent of 3 or 4 per cent., and of course lowering the polarisation that much. Its presence can be determined by dissolving a quantity of the sugar in water, and allowing the solution to stand a few hours, when the citrate of lime will settle to the bottom as a fine white powder.”

Citric acid also makes its appearance in the manufacture of Sorghum sugar.

“Mr. Oma Carr, of the United States Department of Agriculture, has recently examined a scale or deposit from the Sorghum sugar house at Medicine Lodge.

“Except in the proportions of lime and magnesia this is not unlike the scale I have been considering, and the similarity extends to the organic matter, Mr. Carr having found that in this case citric acid was the predominant organic acid.

“I do not consider citric acid a normal constituent of cane juice as ordinarily found in Hawaii, and whether in this case its presence is due to the extremely dry weather or to the fact that the cane is green I cannot tell. An examination of green cane juice during a wet season would throw some light on the question.”

There are two possible explanations of this interesting observation. One is, that the citric acid ferment, which is probably ubiquitous, may have got access to the cane juice in the early stages of sugar manufacture. The other is that the tissues of the sugar-cane may under certain cases act themselves as a citric acid ferment, just as Pasteur has shown that in the absence of oxygen alcohol may be produced in fruits and without the intervention of yeast.—Kew Bulletin.

The Pharmaceutical Journal
FIFTY-FOURTH YEAR OF PUBLICATION.

SATURDAY, OCTOBER 20, 1894.

Editorial Department.
Communications for the Editorial department of the Journal, books for review, &c., must be addressed to the Editor, 17, Bloomsbury Square, London, W.C.

Advertisement Department.
Advertisements and remittances must be sent to "Street Brothers," 5, Savile Street, Lincoln's Inn, London, W.C., where copies of the Journal may be purchased. Cheques and money orders must be made payable to "Street Brothers."

Instructions from Members, Associates, and Students respecting the transmission of the Journal must be sent to the Secretary—Mr. Richard Brenridge,—17, Bloomsbury Square, London, W.C.

PHARMACEUTICAL APOTHECARIES.

Some weeks ago we mentioned the fact of a proposition having been made in reference to the subject of counter prescribing by chemists, that the difficulties associated with this practice might be done away with by establishing a kind of inferior or partial medical qualification, the holder of which would be legally entitled to supplement his duties as a pharmacist by performing certain "emergency duties" of a medical nature. This suggestion, put forward by Sir Benjamin Ward Richardson, was not by any means a novelty, for some years ago, when the Medical Defence Association was endeavouring to enforce a stringent interpretation of the Apothecaries' Act, the idea of legalising a certain amount of medical practice by chemists and druggists was for a time thought to be a feasible mode of removing difficulties existing between medical men and pharmacists. It was, however, at best but a partial remedy, since it dealt with one only of the difficulties, and took no account of the equally serious one of medical dispensing. In any case it does not appear ever to have been favourably regarded by the medical profession, and it may safely be said that with the great majority of pharmacists there was an equal indisposition to seek for such additional privileges as the proposed plan would have conferred. The view entertained by pharmacists in regard to this matter, as it now stands, has recently been well expressed by Mr. Walter Hills in his inaugural address, to the effect that, while ever willing to make use of his knowledge for the relief of suffering, the pharmacist will be anxious not to place himself in a false position and assume a responsibility for which his training and education have not fitted him. We do not imagine that even those who recognise a necessity for higher training to enable the pharmacist to carry out his proper work would desire to supplement that training with additional studies for the sake of occupying an inferior position as medical practitioners.

We have always held the opinion that the maintenance of a suitable distinction between the practice of medicine and that of pharmacy is more a matter to be determined by ethical considerations than by legislation. From the mere legal point of view a chemist and druggist is under no greater disability, in regard to medical practice, than any other member of the community. Everyone is debarred by the Apothecaries' Act from "practising as an apothecary" in the sense that the term apothecary is employed in that Act. But it has been found that the true interpretation of the term "practising as an apothecary" is by no means easy. It must also be remembered that however it may be construed, the Act also contains a proviso that nothing contained in it shall be held to interfere with the business of chemists and druggists as it had been carried on before the passing of the Act. It has been maintained that counter prescribing had long before that time been a regular part of the chemist’s business. Hence the difficulty which Sir Benjamin Richardson refers to as having been experienced by the Medical Defence Association in enforcing the Apothecaries' Act, and hence the desirability of leaving the settlement of the matter to the influence of ethical rather than legal considerations. The natural relations between medicine and pharmacy are the best guarantee that the forms of practice proper to each will not be unduly intruded upon from either side.

But it will be interesting to consider what is the nature of the "counter prescribing" to which Sir Benjamin Richardson refers. From his description of instances in which he considers that the law was broken it may be well understood that throughout the many years he was president of the Medical Defence Association he could never see his way to bring a case of counter prescribing into a court of law as a test case. First of all it is stated that in answering a question whether a pill would purify a chemist would be "illegally trespassing on medical pastures," and would be open to prosecution. It is, however, admitted that no man can sell a drug without subjecting himself to inquiry about what he is selling, and that he would not be considered competent to sell unless he knew something of the properties of the article sold. Naturally that should be the case, and the capability of satisfying such inquiries should be possessed by every chemist and druggist, as distinctly within his province. But strangely enough, Sir Benjamin Richardson holds that "the moment a druggist begins to show such knowledge of his business he technically breaks the law."
emphatically protest against that view as being totally untenable. The other instances given of druggists rendering assistance in cases of dog-bite and sudden bleeding from the nose cannot properly be designated counter practice, though they show how useful the chemist and druggist may be in an emergency. We cannot agree with Sir Benjamin Richardson that they are, in any sense, breaches of the Apothecaries' Act, and his admission that no one would have the temerity to attempt a prosecution in such cases is a practical refutation of that opinion. The necessity for such assistance is in fact the best justification for rendering it, and the educated chemist may be relied upon for such first aid, without being required to enter upon studies which might lead him outside his province, and thus probably increase the confusion of medicine with pharmacy, to lessen which has been the object of recent progress.

AN UNFOUNDED COMPLAINT.

In a note on the sale of poisons in last week's British Journal of Photography, complaint is made of the assumed inaction of the Pharmaceutical Society in regard to poisoning by carbolic acid. It is remarked that the Society is supposed to look after such matters, as it has the power, with the approval of the Privy Council, to regulate the sale of poisons, and in support of the complaint put forward it is added that carbolic acid—a poison which is the cause of numerous deaths—is sold at every oil shop without let or hindrance, and is sometimes given away by sanitary authorities. This is supposed to be altogether inconsistent with the proceedings taken when potassium cyanide is sold by an unqualified person. The anomaly which strikes our contemporary is not, however, due to the cause supposed, and his suggestion that the Society has neglected its duty in regard to carbolic acid has no better foundation than want of acquaintance with the facts of the case.

ACTION FOR SLANDER.

In the Court of Session, Edinburgh, on Tuesday, Lord Wellwood closed the record in an action by William Foster, wholesale draper and oil and colourman, 94, High Street, Edinburgh, against Thomas Keating, insect powder manufacturer, 12, Bride Lane, and two others, partners of the said Thomas Keating. Pursuer sues for £1000 damages. He says that defendants conceived ill will towards the vendors of rival powders, and states that they circulated widely advertisements offering rewards to any one of the public who would give such information as would lead to the conviction of any one who improperly substituted other powder for Keating's. The pursuer alleges that the object of the defendants was, by these means, to get up unfounded actions against traders and others for advertising purposes, and to suppress rival traders in insect powders. The defendants raised an action (see Ph. J. [3], xxiv., 672), against him, and interim interdict was granted in October, 1893, but the action was abandoned. He says the statements made by the defendants on record in that action were false, and were made for the purpose of harassing and tarring his character and reputation and destroying his business. For the defence, it is stated that within recent years the defendants' business had greatly suffered on account of unscrupulous dealers selling, as Keating's powder, powder which was not manufactured by them. They were informed in September, 1893, that the pursuer had repeatedly been guilty of selling as Keating's powder, powder not manufactured by them. An action was raised, but prior to the date fixed for the trial the pursuer, who had originally given them the information intimated that he did not wish to give evidence on account of the publicity it would entail. They pleaded that they acted throughout in good faith, without malice, and that they had reasonable grounds for bringing the note of suspension and interdict into court.

BOURNEMOUTH AND DISTRICT PHARMACEUTICAL ASSOCIATION.

At the first annual meeting of this Association, on Tuesday, October 16, the committee presented a report of the first year's work, which had included some points of business important to the members, and had demonstrated the advantage of such an association. Mr. G. Bridge was re-elected President, and Mr. Hardwick Secretary. A local secretary was then nominated for the Pharmaceutical Society, after which some conversation took place respecting the visit of the British Pharmaceutical Conference to Bournemouth next year. A committee of the whole of the members of the Association was formed for Conference reception purposes, with Mr. Bilson as Treasurer.

DEATH OF ANNUTANTS.

We have received information of the death of Mary B. Rowan, of Plymouth, which occurred on the 12th instant, as the result of injuries accidentally inflicted at the laying of the foundation stone of a local chapel school. Mrs. Rowan was seventy-three years of age, and had been an annuitant on the Benevolent Fund since 1891. We have also to announce the death of Mrs. Martha Short, of Lyndhurst, an annuitant, aged 84, who was elected in 1877. This is the third death of annuitants on the Benevolent Fund within little more than a fortnight.

UNIVERSITY DISTINCTION.

We note that William Griffith, a chemist in business at Barrow-in-Furness, who passed the Minor examination of the Pharmaceutical Society of Great Britain in 1888, has just obtained the degree of M.A. at Durham University.

PRESENTATION AT PLYMOUTH.

Mr. James Cocks, the Honorary Secretary of the Plymouth District Chemists' Association, has been presented with a silver-mounted cigarette case by the members of the junior section of the Association, as an expression of their sense of his efforts on their behalf.

EVENING CLASS IN HISTOLOGY.

We are asked to announce that an evening class in histology will be held in the histological laboratory of the Pharmaceutical Society, 17, Bloomsbury Square, under the direction of the Professor of Materia Medica. A short explanatory lecture will be followed by about two hours' practical work. Particulars of the class may be obtained of the Professor of Materia Medica, 17, Bloomsbury Square, W.C.
Transactions of the Pharmaceutical Society of Great Britain.

DONATIONS.

(Continued from page 299.)

The Curator presented the following report of donations to the Society's Museums and Herbarium:

To the Museum in London:

Mr. H. B. Cox, Shepton Mallet:
Specimens of the fruits of *Carapa guianensis*.

The Pharmaceutical Society:
Specimens of Madras nux-vomica seed.

Sir F. von Mueller, K.C.M.G., M.D., F.R.S., etc., Melbourne:
Fruit of *Balanites grandidens*.

Mr. A. H. Jackson, F.I.C., Melbourne:
Specimen of Ignatia.

Dr. Geo. Watt, C.L.R., Calcutta:
Leaves of *Gymnema Sylvestre*.

Mesrhr. T. Christie and Co.:
Specimen of "Silnulo" fruits.

Mr. R. Thomson, Bogota:
Specimen of bark from U.S. Colombia.

Mr. J. H. Hart, F.L.S., Botanic Gardens, Trinidad:
Specimen of dried Coia nuts cultivated in Trinidad.

Dr. J. R. T. Altheism, C.L.R., F.R.S.:
Specimen of Asafoetida collected in Kashmir from the stems of *Ferula nartheca*.

To the Museum in Edinburgh:

Mr. J. Wight, Edinburgh:
Specimen of sterile Orpiment in crystals from Aghanistan, N.W. Persia.

Meshr., Dunnan, Flockhart & Co.:
Follicles of *Strophanthus Tigridius*.

To the Herbarium:

The Director, Botanic Gardens, Jamaica:
Specimen of *Aloc variegata*.

Sir F. von Mueller, K.C.M.G., M.D., F.R.S., etc.:
Eleven specimens of Australian plants.

Mr. J. G. Hay Wood, Botanic Gardens, Natal:
Fifteen specimens of South African medicinal plants.

Mr. R. Thomson, Bogota:
Specimen of *Cinchona pombianca* with flowers and fruits.

Mr. R. J. Lydech, F.L.S., Botanic Gardens, Cambridge:
Flowering specimen of *Piloporus jaborandi*.

The Curator:
Specimens of *Tenorium chamaedryis* and *Stachys germanica*, from Oxfordshire.

American Pharmaceutical Association.

The forty-second meeting, at Asheville, N.C., which was continued from September 3 to 8, proved very enjoyable and profitable to a numerous attendance. The address of the president, Professor Patch, was delivered on the afternoon of the first day, and contained many valuable suggestions. He did not take a very rosy view of the condition of the drug trade in the United States, where, as in Canada, it is very much overdone. He thought that with about one-third the existing number of druggists, and one-sixth of doctors, people generally would be better off—an opinion which met general approval, as every pharmacist at once clasped himself with the lucky third, and his neighbour with the unfortunate balance. Professor Patch recommended to the Association an inquiry into the necessity for the establishment of a pharmacy com-
mission, and the substitution of a national law for the various State enactments, so that educational requirements would be the same all over the Union. He suggested that a course of instruction in pharmacy be prescribed for the course of pharmaceutical colleges, and also proposed the establishment of a scholarship fund, of an annual value of $1500, to assist those who wished to take an advanced course abroad.

The total membership of the Association was announced to be 1534. The financial statement showed the receipts for the year to have been $12,184.98, which showed an increase in the balance of $5,191.14 of the previous term. The disbursements amounted to $7,851.96, the heaviest item being $4,541.67 for the International Congress at the Chicago Fair.

Various places for the next meeting were suggested, among others, Montreal, but finally Denver was chosen. The election of officers was effected by the acceptance of the ticket of the nominating committee, by which Mr. W. Simpson, of North Carolina, becomes president; Mr. C. M. Ford, Denver, first vice-president; Mr. J. V. Hurty, Indianapolis, second vice-president; and Mr. W. M. Morrison, Quebec, third vice-president. Mr. S. A. D. Sheppard continues in the office of treasurer, which he has so long held, with Mr. C. Caspari as permanent secretary, and Mr. Knaemel, reporter on the progress of pharmacy.

Probably the most lengthy and animated discussion related to the subject of "free alcohol." At the last session of Congress an amendment was offered by Senator Hoar, and carried, that any manufacturer using alcohol in the arts, or in any medicinal, or other like compound, shall, under certain conditions, be entitled to a rebate of the duty on spirit so used. The Commissioner of Internal Revenue has found it very difficult to draft regulations in regard to this matter, and to define exactly what is meant by the terms "manufacturer" and "any medicinal or other like compound." A resolution commending the action of Congress for legislating favourably in regard to free alcohol was offered by a member of the Association; but this was objected to on the ground that the meaning of the privilege was not yet understood, and a committee was appointed to consider the subject. They reported to the effect that the regulation and control of alcohol for manufacturing and medicinal purposes was in a broad sense practically impossible. They protested against any interpretation of the act except that which would exempt alcohol used in the manufacture of such products as show an entire change of chemical and physical properties—such as ether, chloral, and chloroform. This naturally aroused the retail element, as druggists would thus be cut off from any participation in the advantages of the new regulations. A very serious debate followed, but the recommendation of the committee was carried.

The question of cut rates was brought before the Association, and, after the usual modes of meeting the difficulty had been brought forward and talked over, it was resolved that the Association endorse the views of the Interstate Retail Druggists' League, by which the contracting parties agree to withdraw their patronage from those who knowingly supply cutters with goods of any description, and also agree to discontinue the sale of any patent or proprietary articles furnished by or on behalf of their agents. Whether the A. P. A. is to be bound by this resolution, or the individual members of the body, or whether the action is to have any practical effect, is not clear.

At a late stage of the meeting the subject of "pharmacists' supply" houses was brought forward, and resolutions were adopted condemning the practice of manufacturing pharmacists selling ready-made medi-
CHEMISTS' ASSISTANTS' ASSOCIATION.

A musical and social evening was held at 103, Gt. Russell Street, on Thursday, 11th Inst., when the chair was occupied by Mr. S. M. Burroughs. The entertainment was under the direction of Mr. G. Roe, and was thoroughly enjoyed by the large number of members present.

PHARMACEUTICAL FOOTBALL AND CRICKET CLUB.

A general meeting was held at 17, Bloomsbury Square, on Monday, October 15, for the election of officers. The result of the ballot was as follows:

- Captain, Mr. F. K. Allen; Vice-Captain, Mr. A. Lilly; Committee, Messrs. Brown, Moore, Skinner, Walker, Woodraff; Honorary Treasurer, Mr. G. E. Jones; and Honorary Secretary, Mr. Tickle.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

OPENING OF THE SCHOOL OF PHARMACY.

The usual gathering to inaugurate the winter session of the Sheffield School of Pharmacy was held on Thursday, October 11, at the Cutlers' Hall, Sheffield, and was followed by the annual dinner of the Sheffield Pharmaceutical and Chemical Society. The chief feature of the first-named event was an address to the students by Mr. Charles B. Allen, of London, member of Council of the Pharmaceutical Society, which has already appeared in our columns (ante, p. 303). The President of the Society, Mr. J. F. Kardley, occupied the chair, and there was a good attendance, including most of the officers of the Society and several pharmacists from a distance.

Mr. G. Squire, Hon. Sec. of the Society, announced that he had received letters apologising for absence from Mr. M. Carteigh, President of the Pharmaceutical Society; Mr. R. Bremside, Secretary to the Pharmaceutical Society; Drs. Snell, Martin, Burgess, Littlejohn; and Mr. Geo. S. Woolley, President of the Manchester Pharmaceutical Society; and W. Smith, President of the Sheffield Literary and Philosophical Society; Dr. Paul, Editor of the Pharmaceutical Journal, the Editor of the British and Colonial Druggist, and Mr. A. H. Allen, city analyst.

Mr. C. O. Morrison, Hon. School Secretary, then read the following report of the school for the session 1893-94. "The number of entries in the classes of the school during the last session was twenty-six. The lecturers (Mr. J. Austen and Mr. J. C. Platt, F.C.S.) report that the progress made by the students has been satisfactory, whilst the attendance throughout the session shows an average of 89 per cent. It may be stated that the classes are held at night after business hours, and on the Thursday half-holiday. On the last-named day, when apprentices might be excused for using the time for other purposes, the average attendance at the two chemistry classes has been 86 per cent., which affords strong evidence that the students appreciate the efforts made on their behalf. The following were the prize-winners: Materia Medica, Council prize, W. H. Ludlam, lecturer’s prize, H. J. Morris; Botany, Council prize, A. Exell, lecturer’s prize, J. E. S. Milligan; Chemistry, Council prize, H. J. Morris, lecturer’s prize, A. Wager; Practical Chemistry, Council prize, F. A. Telford, lecturer’s prize, A. Wager; President’s prize for all subjects, W. H. Ludlam and W. E. Pigott, equal. The Chairman said he was glad that the attendance at the school had been so good. It was very gratifying.
ing when they remembered that the students gave up their evenings to the classes, and also their half-holidays. If apprentices in their early days wished to attend the classes regularly, they would not find so much difficulty in the examination room as at present, and they would not hear so much about the examiners, because those gentlemen, on probing beneath the surface, would find a solid foundation instead of mere phrases. Among the students present in their school five years ago there was scarcely one to-day who was not qualified. It was a matter of great satisfaction to the older members of the Society to know that former students of the school were now taking upon themselves the active work and duties of the Society. Their present secretary was a former student in the school.

The prizes, consisting of well-known scientific works of value to the student, were then distributed, after which Mr. C. B. Allen delivered his address (ante, p. 303).

Professor Greenish, in proposing a vote of thanks to Mr. Allen, said it had been his fortune in the course of some years to listen to addresses and addresses, but he could honestly say he never listened to one which had given him more satisfaction and pleasure than that delivered by Mr. Allen. Mr. Allen and himself had had frequent talks about education, and on such matters were much the same. He cordially endorsed the advice which Mr. Allen had given to the students. As a teacher at Bloomsbury Square he knew that one of the principal difficulties of the staff there lay in the fact that students were brought before them with a very slender foundation of knowledge to build upon, and the teachers were confronted with the difficulty of endeavouring to compress into a very few months an education that ought to extend over a very much longer period. If apprentices and students, especially apprentices, when they first entered the business would begin at once to lay a foundation on which a structure might be raised in later days, it would not only facilitate the work of the teachers, but would be of immense benefit to themselves. If students would enter into familiar intercourse with their teachers, as advised by Mr. Allen, they would derive much benefit therefrom. It was a great pity that they regarded their teachers not as men who wished to help them, but rather as persons from whom they were obliged to learn.

Mr. G. Owen, in seconding the motion, raised a laugh by remarking that student life had been painted in such glowing colours that it made some of them who were getting on in years almost wish to go through it again.

The Rev. T. S. King, in supporting the vote, said it was an exceedingly thoughtful, intellectual and business-like address that they had been privileged to hear. There had been crowded into it food enough for satisfaction until they opened their session again next year. If the students would act upon the advice which had been given to them they would grow up very happy in their profession and very useful in their day and generation. The address had been stimulative and inspiring. The danger nowadays was that they should pay too much attention to the bookish that they began to think that the obligation was on the side of their teachers and helpers, rather than the other way. In conclusion, Mr. King congratulated Mr. Earley on his election as President of the Society, and said he hoped his year of office would be a happy and a successful one.

The vote was carried with acclamation.

Mr. Allen, in responding, said he had told the students nothing but what to some extent was the outcome of his own experience. He was satisfied that the great weakness in pharmaceutical education was that sufficient time was not devoted to it. Their qualification should follow as a sequel to other things. When they had gained their qualification they would readily admit that that, after all, was not the great end of study. The meeting then terminated.

The Annual Dinner.

Subsequently, in the old banqueting chamber of the Cutlers' Hall, the annual dinner of the Society was held, and was well attended. Mr. J. F. Earley presided, and amongst those present were Mr. Charles B. Allen (London), Mr. J. Rymer Young (Warrington), Professor Greenish (London), Mr. Edmund White, B.Sc. (London), Professor Arnold, Mr. John Humphrey (Pharmaceutical Journal), Mr. S. T. Rhodes, and Mr. G. Owen, Vice-Presidents of the Society, Mr. G. T. W. Newsholme, Treasurer, Mr. G. G. Squire, Hon. Secretary, Mr. C. O. Morrison, Hon. School Secretary, Mr. G. Ellinor, Mr. A. R. Fox, Mr. J. P. Hewitt, Mr. H. E. Ibbitt, Mr. J. Preston, Mr. W. Ward, Mr. C. H. Hewitt, Mr. W. Dale James, M.R.C.S., and Mr. J. H. Worral.

The loyal toast having been honoured, Mr. C. B. Allen proposed "The Sheffield Pharmaceutical and Chemical Society." He said a perusal of the syllabus for the current session reminded him that he was the first member of the Pharmaceutical Council who had come to inaugurate the session of the Sheffield School of Pharmacy—a proof of the loyalty felt amongst the pharmacists of that city for the Council. They all lived close enough to Bramall Lane to know the significance of the ninth man. He was not yet at his score. Shortly after his election to the Pharmaceutical Council he was in a railway train with other members of the same calling. The conversation turned on the election of members to the Council, and one gentleman said, "I always begin by scratch ing out all the Londoners; they are no good." He did not ask him for his definition of a Londoner, but he (Mr. Allen) found that in London anything like local spirit or local action was almost entirely wanting. A Londoner was imperial if they liked, but in anything local he was altogether handicapped. He hardly knew what his own district was, and even if he would define it, he suspected he was beyond his power to meet those of the same vocation within it. It was, therefore, very difficult to get local action. He wanted to impress upon those chemists who employed apprentices the importance of educating them for the vocation to which they were called. It seemed to him there could be no better bond of union than an association of master and apprentice in the interests of education. The career of the apprentice or pupil was bound up with the master, and it behoved every man who took pupils for the serious and responsible calling of pharmacy to be sure that at the outset of their career he recommended them to be beyond his power to meet those of the same vocation within it. The practical training of the apprentice lay within the daily work of the pharmacist, but his technical training was not so easy. The existence, however, of the School of Pharmacy in Sheffield did away with the difficulty, and he appealed the better to see that his apprentices attended the school.

The President, in responding, said Mr. Allen's allusion to the "ninth man" was a very happy one, because they all knew from their cricketing experience of the past season that the ninth man at Bramall Lane had often been the mainstay of the club. Their Society in Sheffield had three bases. That of their objects was to promote a feeling of fellowship amongst them. By their monthly meetings the Council tried to place before the members something instructive
and useful, and he wished masters would turn up to them the same as to the annual dinner. He considered the main object of the Society was to promote the education of apprentices. He would like to see the curriculum. He knew many masters did not approve of it, but when they got the curriculum they would not have so many complaints about the examiners. His experience of the examiners was that they were kind to the students and they were bound to be "plucked" on going before certain examiners, but his experience was that line, and had a position such as no other tradesman enjoyed. The work of the Council of the Society was recognised by such a distinguished body as the Royal Society, and one of the oldest London companies—the Salters' Company. Both had given help, showing that the Society must have attained a splendid position. Although it only numbered one-third of the chemists of the country, it was legislating for the whole of the chemists of the kingdom. In conclusion, Mr. Newsholme said in Sheffield they were loyal to the Society.

Mr. J. Rymer Young, who also replied, said he did not appear in any way as an apostate for the Pharmaceutical Society, nor was he in a position to go into the questions which Mr. Ibbitt had raised. Mr. Newsholme had very effectually dealt with the matter, but there was no reason why he should not tell Mr. Ibbitt that what he took to be the head and front of his complaint—competing trades—hit every member of the Pharmaceutical Society, and it hit the proposer of the toast. If by any Act they could obliterate that nightmare it would be done, but they had no powers beyond the statutes they now possessed. Hundreds of most important Bills in Parliament were shelved for want of time, and under those circumstances it was within the range of what was practical to introduce at the present time an amended Pharmacy Act which should contain provisions such as had been suggested by Mr. Ibbitt? The Council of the Society consisted of men who were doing their level best to remedy the evils with which pharmacists were surrounded, and to make the lot of the average pharmacist better. He had been struck at the assiduity and persistence with which members of the Council had sacrificed their time in the interests of the pharmaceutical community, and he had also been struck with the deplorable ignorance and the astounding apathy which seemed to pervade the moral atmosphere of the world and to shut the eyes of a privileged class of people to regard the Society as a sort of football, to be kicked by everybody who happened to have lost a customer through competitive trade. While he had no sympathy with such conduct, he was inclined to think it would be wise to occasionally alter the complexion and constitution of the Council by the infusion of a little new blood. At the same time, he would recommend them in Sheffield not to part with their present representative on the Council sooner than they could help. It would be a pleasure to the members of the Council to think of the night that in their festivities, as in their work, they lived in the hope that it would be the constant endeavour of the Council to anticipate and fulfil the wishes of their constituents.

Mr. C. O. Morrison, in a humorous speech, proposed the health of the examiners and professors of the Pharmaceutical Society of Great Britain. He spoke of the men of science that they were, and of the work they did, and said he believed such professors as Mr. Greenish would do all in their power to impart that knowledge to the students which would be a benefit to them and the community, and that examiners such as Mr. White would do everything in their power to do that which was required of them. It was a public service.

Professor Greenish, in replying, said there was a suggestion some time ago that the school in Bloomsbury Square was scarcely any longer a necessity. He
vented to differ with those who took that view, and he thought he had the Council of the Society with him. The Council had persistently and systematically advocated education. Having pointed out the tendency of the instruction given at Bloomsbury Square, the professor said that whether the teaching staff would succeed in giving students an education equal to the demands and wishes of the Council remained to be seen; but only he who believes that it was the earnest endeavour of every member of the teaching staff to render that a fact, and not simply a possibility.

Mr. White, who also replied, said some contended that the examiners were a bad lot, but it was generally the unsuccessful candidates who took that view. He could assure them that every member of the Examining Board approached a candidate, not with a desire to pluck him, but with a desire to bring out his knowledge to the best advantage.

Several minor toasts followed, and the company dispersed at a late hour.

PLYMOUTH AND DISTRICT CHEMISTS' ASSOCIATION.

ANNUAL MEETING AND DINNER.

The annual business meeting of this Association was held at the Plymouth Hotel, Plymouth, on Wednesday, October 10, at 2.30 p.m., for the election of officers for the ensuing year, and other business. The chair was taken by Mr. J. G. Netting, President.

The following was the result of the voting:

President, Mr. C. J. Park; Vice-Presidents, Messrs. G. Breese and J. G. Netting; other Members of Committee, Messrs. Freemantle, W. Hunt, J. D. Turner, A. D. Breese, P. Kelly, Martin Johnson, and F. Maltland; Auditors, Messrs. C. Menhinick, and J. Barge; Hon. Treasurer, Mr. J. Harvey Bailey; Hon. Sec., Mr. James Cooks.

Fifteen new members were elected, and two honorary members. The Treasurer and Secretary's reports were adopted, and the outlook for the ensuing year was considered very satisfactory.

The first annual dinner was afterwards held at Matthew's Restaurant, Mr. J. G. Netting (President) being supported in the chair by the Mayor of Devonport (Mr. G. Waycott), the chairman of Stonehouse Local Board (Mr. W. W. Blight), and other guests. During dinner a programme of music was efficiently rendered by an orchestra under Mr. J. N. Pearce.

The loyal toasts having been honoured, Mr. J. D. Turner proposed "The Pharmaceutical Society." He spoke at length of the objects and benefits of the Pharmaceutical Society, and said sympathy should exist between every chemist in the country. Those who were interested and watched the gradual growth of the Society, particularly from an educational point of view, had need to be proud. They all felt it was a matter of great satisfaction, that in the hands of such a worthy president as Mr. Cartelgh.

In responding, Mr. Rendle dealt with the sale of poisons and drugs generally. They must show Parliament, he said, that their interests were identical with those of the public. It would be a safeguard to the public if the sale of poisons was limited to qualified chemists.

In supporting Mr. Rendle, Mr. Hunt hoped the Society would continue to do the good work it had done in the past. Throughout the country there were 20,000 chemists, and at the present time only 4,000, or a fifth of that number, were members of the Society. Until they obtained a larger footing it would be useless presenting bills to Parliament.

The toast of "The Plymouth, Devonport, Stonehouse, and District Chemists' Association" was proposed by Mr. W. W. Blight, who said the object of the Association was strictly educational. The pharmacists should take advantage of that, and make their employers efficient. Very few professions laid themselves out as they did in Plymouth, and it was a great pity such was the case.

The President (Mr. Netting), responding, said the officers during the past year had done their best to bring the Association up to the standard they had set, and hoped the future officers would eclipse the efforts of the past. He should ever regard it as a great honour to have been their first president. He spoke very highly of their energetic secretary, Mr. J. Cocks, and he felt sure their future president, Mr. C. J. Park, would do his utmost to serve them.

Other toasts followed, the toast of the officers of the Association being responded to by Messrs. J. Harvey Bailey and James Cocks.

LIVERPOOL CHEMISTS' ASSOCIATION.

Under the auspices of this Association a conversation was held at the Royal Institution on October 11, to inaugurate the forty-fifth winter session. Mr. J. J. Smith presided, and there were also present, amongst a large number of members, Messrs. Bain and Conroy, Vice-Presidents, and Messrs. J. Smith and Anthony S. Buck, Honorary Secretaries. The programme consisted of vocal and instrumental music, in which Mr. Luddell, Mr. Bain, Mr. Delaville, Miss Nancy Rigby, Miss Edith Lucas, and Miss Sharp took part, and a lecture by Mr. A. T. Smith, Secretary of the Microscopical Society, entitled "A Drop of Water as seen through a Lantern Microscope." During the evening the visitors examined a number of interesting exhibits lent for the evening by members of the Association.

BRIGHTON JUNIOR ASSOCIATION OF PHARMACY.

A musical and social meeting in connection with this Association was held on Wednesday, October 10, at the headquarters, 2, Stowel Terrace, under the chairmanship of Mr. C. G. Yates (the President). There was a good attendance, and, owing to the indefatigable energy of the Hon. Secretary, Mr. F. A. Crowhurst, an enjoyable evening was spent. The programme included a recital on the piano by Messrs. A. E. Collins, J. E. Lander, H. G. Price, A. Smith, H. E. Hodgcock, Bridgewood, Cupitt, and A. Collins.

MEETING OF NOTTINGHAM CHEMISTS' ASSISTANTS.

The Nottingham chemists' assistants and apprentices held a soirée and smoking concert at the Eagle Restaurant on Thursday, October 11. There was a fairly good attendance. The proceedings opened with an overture by Mr. H. Woodhouse, and, following this, songs, violin solos, etc., were satisfactorily rendered by Messrs. C. Gilliatt, H. Wilford, J. E. Pickerill, T. Mason, T. Goddard, and R. H. Beverley. The proceedings, which were of a most enjoyable nature throughout, were ably presided over by Mr. T. Mason.

Dispensing Memoranda. — [681.] In reply to the communication on page 168, a correspondent writes as follows:—"The reaction in this prescription is simple. The sodium bicarbonate and calcium hypophosphite react, producing calcium carbonate, sodium hypophosphite, and free carbonic acid gas which escapes, forming a copious froth. Apparently no secondary decomposition takes place."
PROCEEDINGS UNDER THE PHARMACY ACTS.

SALE OF OPium BY AN UNREGISTERED PERSON.

At the Bloomsbury County Court on Wednesday, October 17, before His Honour Judge Bacon, the Pharmaceutical Society sued W. F. Mundy, Managing Director of the Empire Drug Co., Ltd., 258A, Mare Street, Hackney, N.E., for five penalties of 25 each for selling poison contrary to the provisions of the Pharmacy Act, 1868.

Mr. Grey (instructed by Messrs. Flux, Thompson and Flux) appeared as counsel for the Pharmaceutical Society; Mr. H. C. Richards, instructed by Mr. Rawlinson, appeared as counsel for the defendant.

Mr. Grey: May it please your Honour, this is an action to recover five penalties from the defendant, Mr. W. F. Mundy, for selling poison contrary to the Pharmacy Act, 31 and 32 Vic.

The Judge: Do you wish me to take a note of this case?

Mr. Grey: If you please, sir.

Mr. Richards: It is only a question of fact; there is no law in dispute.

The Judge: I should have thought at this stage of the history of this litigation between the Pharmaceutical Society and unregistered people it must be all a question of fact.

Mr. Richards: Yes, sir; we have paid £10 before, because we knew we were offenders, but this time we are fighting the Society on the facts.

Mr. Grey: The defendant carries on business under the title of the Empire Drug Co., Ltd., at 258A, Mare Street, Hackney, and on the dates mentioned in the particulars a prescription was handed in to him to be made up, and in that prescription there is twenty minims of tincture of opium, and in a liniment that was made up at the same time there is half a fluid ounce of opium liniment. Those prescriptions were made up by the defendant, and were sold in the bottles with which I will now identify the defendant was alone in the shop, and actually made it up in the presence of a witness whom I shall call. The medicine was supplied in a bottle with this label: "The Empire Drug Co., Ltd., 258A, Mare Street, Hackney. Prescriptions prepared with the utmost care from the very best drugs obtainable. Store prices for cash." "The liniment is for external use, to be well rubbed in. Shake the bottle." Those bottles were handed to the analyst, and the analyst will tell you that, as regards the medicine, they contained as nearly as possible twenty minims of tincture of opium, and, as regards the liniment, half a fluid ounce of opium liniment. The Act under which we are suing is the 31 and 32 Vic., cap. 21, section 1 of which makes it "unlawful for any person to sell or keep open shop for retailing, dispensing, or compounding poisons, or to assume or use the title "chemist and druggist," etc., "unless such person shall be a pharmaceutical chemist or a chemist and druggist within the meaning of this Act, and be registered under this Act." Section 2 says: "The several articles named or described in the schedule (A) shall be deemed to be poisons within the meaning of this Act." Under schedule A you will find opium, the very last poison mentioned, and all preparations of opium or poppies. Then the printed register is evidence before you by section 18, which says: "The absence of the name of any person from such printed register shall be evidence, until the contrary shall be made to appear, that such person is not registered according to the provisions of the Pharmacy Act or this Act." This gentleman's name does not appear in the register. Section 15 is the important section, which says that "any person who shall sell, or keep an open shop for the retailing, dispensing, or compounding poisons, or who shall take, use, or exhibit the name or title of chemist and druggist, or chemist or druggist," etc., "shall for every such offence be liable to pay a penalty or sum of £5, and the same may be sued for, recovered, and dealt with in the manner provided by the Pharmacy Act." Then the Act says the Pharmaceutical Society are to sue for those penalties. I will now only call your attention to two cases.

Mr. Richards: I do not dispute any of these proceedings.

The Judge: Mr. Richards says his defence depends on the facts.

Mr. Richards: I do not dispute any of my learned friend's propositions up to the present.

Mr. Grey: The Pharmaceutical Society v. Wheeldon, which is reported to be Q.C. D., decides that the person who compounds the poison, or makes it up, or even sells it across the counter, is the person liable to a penalty under the Act.

Mrs. Sarah Partridge, examined by Mr. Grey: Where do you reside?—Brixton.

The Judge: You are the wife of whom?—John Partridge.

What is he?—A commission agent.

Mr. Grey: Were you instructed by the Pharmaceutical Society to go to No. 258A, Mare Street, Hackney?

—I was.

When did you go there?—On June 1.

What was it? Was it a shop?—It was a chemist's shop.

What was it called?—The Empire Drug Co.

Did you go in there?—Yes.

Whom did you see?—The defendant, Mr. Mundy.

Mr. Richards: That is admitted.

Mr. Grey: What did you ask him for?—I handed him a prescription.

Will you look at that? (hanging a paper). Is that the prescription you handed to him?—Yes.

Did he make it up for you?—Yes.

What did he hand you?—Two bottles.

(The witness identified two bottles.)

What did you pay for them?—10d.

Did you then take them home with you?—Yes.

What did you do with them?—I sealed them up.

Did you go again to the same shop?—Yes.

What day was that?—June 12.

What did you do then?—I handed the same prescription to the defendant.

Did he make it up the same as before?—Yes.

Did you pay him for it and take the bottles home?—Yes, I paid him 11d.

(Witness identified two bottles.)

Did you go again to the same shop?—Yes.

What was it that?—June 16.

Did you do the same thing again?—Yes.

(Witness identified two bottles.)

Did you go again to the same shop?—Yes.

The Judge: How often is she to go to the same shop?—Is it to accumulate penalties?

Mr. Richards: That is it.

Mr. Grey: Did the defendant serve you with those?

—Yes.

Did you go again, a fifth time?—Yes.

That was the same prescription?—Yes.

Did you seal up those bottles the same as the others?—I did.

What did you do with them afterwards?—I handed them over to the analyst.

What is his name?—Mr. Eastes.

In what condition were they when you handed them over?—Sealed.
You say you sealed them all—
The Judge: You did not ask her if she sealed them on each occasion. You only asked her as to the first and last occasions.
Mr. Grey: No, because she said she had done the same thing on each occasion.
Cross-examined by Mr. Richards: How long have you been doing this work for the Pharmaceutical Society, Mrs. Partridge?—The first time I made a purchase for them was about twelve months ago.
Is your husband connected with that body?—He has made purchases for them at times.
Who do you call him a commission agent?—Because he has several agencies for cattle food, and for Devonshire cider.
You know that some weed killer has been held to be a poison. Have you been buying any of that?—I have not.
Were you the lady who bought the poisons when Mr. Mundy paid the penalties some time ago?—I made one purchase.
Who sent you definitely on June 1 to this shop?—A representative of the Pharmaceutical Society.
I want to know his name?—Mr. Moon. Who put it to him?—He is an officer of the Pharmaceutical Society.
Did he give you this prescription marked "Mrs. Monroe’s little boy"?—No.
Who put on this prescription "Mrs. Monroe’s little boy"?—The person who wrote the prescription.
Who was that?—I do not know his name. He is a chemist.
Is he a chemist in Hackney?—Yes.
Where was this prescription written?—I do not know.
Did the person who wrote the prescription, or by Mr. Moon?—No, it was not given to me by the person who wrote it, or by Mr. Moon.
Then how do you know it was written by a chemist in Hackney?—My husband obtained it from chemist in Hackney.
When you went into the shop on the first occasion you saw Mr. Mundy?—Yes.
Did you see him write in the prescription book before he proceeded to dispense the medicine?—I did not see him writing, but he was at the desk.
Did he not say to you that he could not give you tincture of opium, but that he could give you tincture of lobelia?—No, nothing of the kind was said.
Was there anything said?—Yes.
Do you swear that?—I do.
Was there no conversation at all?—He said it would take some time to make it up; would I wait or call again.
What did you say?—I said I would call again.
I put it to you that he said to you that he could not dispense tincture of opium, but he would give you tincture of lobelia, which was the same thing?—Nothing of the kind whatever.
Did you bring an old bottle to the shop?—No.
They were fresh bottles on each occasion?—Yes.
That you are quite certain about that?—Quite certain.
I put it to you that on the first occasion you brought one of these bottles to the shop?—No, I did not.
Your husband gave you the prescription; when, in the morning?—In the afternoon.
At Brixton or at Hackney?—At Hackney.
Where?—Just outside the defendant’s shop.
Did he bring it out from an adjoining chemist’s, Mr. Harley’s shop?—No.
Did you go with your husband into a chemist’s shop in Hackney after you got the prescription?—He accompanied me to Hackney. We walked about Hackney.
After you had got your two bottles on June 1 where did you meet your husband after you came out of the shop?—A few doors from the defendant’s shop.
Did you not go then to a chemist’s in Hackney?—No.
Where did you go then?—We went to Leighton, in Essex.
On the same business?—No, to visit some friends.
What did you do with the two bottles after you brought them out of the shop?—Kept them in my coat pocket.
You went to your friends, and, I suppose, had some tea?—No.
Nor supper?—No.
You came back all the way to Brixton without any refreshment of any kind?—No.
When you got back to Brixton what did you do with the two bottles?—I sealed them.
You did, or your husband?—I did, in my husband’s presence. I kept them upstairs in my room, locked up.
When were they handed to Mr. Essees?—On July 9.
I suppose at that time you had got all these ten bottles together?—Yes.
Is your husband here?—Yes.
Is he going to be called?—I have not heard.
Will you take your oath that you sealed each of these bottles on the same day that you took them away from Mr. Mundy’s shop?—I will.
The next time you went was on June 12?—Yes.
You perfectly recollect that nothing was said about the substitution of something for tincture of opium?—Nothing whatever.
Who sent you on the 12th?—I had instructions to make so many purchases. I went when I felt inclined.
Mr. Mundy’s shop was not the only one you visited?—Mr. Moon?—Yes. I went when it was convenient to myself.
The Judge: Were you directed to get five specimens from Mundy?—Yes.
By Mr. Moon?—Yes. I went when it was convenient to myself.
The Judge: I suppose you considered that was enough for a few days for Mrs. Monroe’s little boy.
Mr. Richards: I want to know whether your husband went with you on any other occasion?—Yes.
On each occasion?—No.
On which occasion?—The 23rd.
As a matter of fact, when you went with you he was not waiting for you in an adjacent chemist’s shop?—No.
Have you ever gone into a chemist’s shop when you were going to make these purchases?—Yes; Mr. Watson’s.
Were you going to take proceedings against that unfortunate man?—The Pharmaceutical Society must decide that, sir.
I put it to you that you went to a chemist’s shop near, who is a member of the Pharmaceutical Society, and that that used to be the trysting place of you and your husband; do you deny that?—I do.
Did you not go to Mr. Harley’s shop on any of these occasions?—No, I have been there.
Were you there on June 1?—No.
On the 12th?—No.
On the 23rd?—I might have been, but I cannot remember. I went there to have two teeth extracted.
At that, of course, you would make a lasting remembrance on anybody, having their teeth taken out by a chemist?—He was a dentist as well.
You say you kept these bottles in your house from June 1 to July 9?—Yes.
Will you swear that on each occasion they were sealed on the day you brought them home?—I will.
Mr. Grey: I may say Mr. Partridge is here if my
friend wants to ask him any questions. I do not propose to call him, as he does not carry the case any farther.

Mr. Richards: I do not wish to see him unless my friend puts him in the box.

Mr. Ernest John Eastes, examined by Mr. Grey:—
Are you an analyst?—I am.
A Fellow of the Institute of Chemistry and assistant to Professor Attfield?—Yes.
Do you receive from the last witness the bottles that have been put in?—I did.
How many were there altogether?—There were ten in all.

In what condition were they?—They were sealed. Were they also marked?—Yes, with the dates of purchase.
Taking the first two bottles—June 1—what did you do with them?—I analysed them.
Tell his Honour the result of that analysis—first, as to the liniment—I found it to contain, amongst other constituents, opium.
How much?—I did not take the quantity, but there was a considerable amount.
Did you see the prescription?—I did.
Was the liniment made according to the prescription?—To the best of my belief it was.
Did you also analyse the other bottle—the medicine?—Yes.
Did you see the prescription of that?—I did.
Was it made in accordance with the prescription?—I cannot say with regard to all the ingredients; I only analysed for one ingredient. I searched and found morphine.

What is morphine?—The chief constituent of opium. I was not able to determine if the morphine were introduced as a preparation of opium or a preparation of morphia.
Morphine is the principal alkaloid?—Yes, it is the alkaloid to which the toxic effects of opium are chiefly due. The small amount, and the presence of the other ingredients, interfered with testing for the other constituents of opium.
Did you then analyse the other bottles in turn?—Take the second bottle, June 12, the liniment?—Yes.
Did you analyse that?—I did.
What did you find that contain?—It was similar to the last, and in this one I determined the actual amount of morphine.
